## ADDRESSES.

### THE PRESIDENT'S ADDRESS.

*Delivered at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June 25, 1889.*

BY W. W. DAWSON, M.D.,  
OF CINCINNATI.

The Premier, Mr. Gladstone, after quoting the statistician who estimates the English-speaking people at the close of the next century at one thousand millions, says: "What a prospect is that of many millions of people, certainly among the most manful and energetic in the world, occupying one great continent." This destiny in numbers is startling, but the assertion of Dr. Dolinger, a German scholar, portrays the culture of the future almost as strikingly when he says "that the intellectual primacy of the whole world is certain to fall to the Anglo-Saxon race." Most of that race will be in America.

Looking to such a future the position of the learned professions is certainly conspicuous—their obligations imperious. Medical men should be loyal to this grand destiny.

An eminent modern critic, in discussing civilization in America, while admitting that we have well solved the political and social problems, asks what have we done to solve the human problem, "the humanization of man in society." The struggle in his own country, he asserts, has resulted in "an upper class materialized, a middle class vulgarized, a lower class brutalized."

We trust that our efforts have yielded better fruit; and since medical science and medical men are prominent factors in society, among every people, we may well ask, what have they accomplished, what part they have here taken in the solution of the vital problem? In the "Century of Medicine," Prof. E. W. Clark in his classical address says:

"It is not an extravagant assertion to say, that in all this turmoil, change and progress (referring to the revolutions and changes in society, religion and government for the past century), medicine has kept abreast of the other natural sciences, of politics, and of theology, and has made equal conquest over authority, error and tradition," and it may be added, has contributed largely to man's

comfort, happiness and advancement. To intensify this, reference need only be made to some of our triumphs, to Vaccination, to Anaesthesia, to Sanitation, the prevention of pestilence, the lengthening of human life. It is, however, more especially the contributions of the profession in America to which attention is desired at this time. What are we doing in the humanization of man, in the work of civilization?

Are our medical practitioners and our medical teachers what they should be? We shall see. Criticisms abound concerning the defects of medical education. Those who do not condemn, often ridicule. These criticisms and strictures are made for the most part, it must be said, by gentlemen unacquainted with teaching, without any practical knowledge of the constitution of medical colleges, or of the toil, devotion and sacrifice made necessary by those engaged in didactic and clinical instruction.

These censorious addresses are delivered before and to a body of professional gentlemen, the peers of any, some of whom have grown gray in the hard service, others are still in the prime of life, with reputations coextensive with civilization. The rest are young, full of life and enthusiasm, fired with ambition to render loyal service to that profession which they have chosen. Can our system be so defective? The pessimistic orator seems to forget that he is the product of the system of medical education which he is so severely condemning. Some one has said, "By retrospection and introspection an individual, like a profession, may be benefited." In this self-examination we should have but one motive, the elimination of error, the development and support of truth.

Education cannot make all great or equal. It tends, however, to make all safe. In the crucible of private, practical life, evolution asserts itself and the fittest survive.

In making a retrospect of our profession it may be well to look for a moment at medical teaching in this country.

The way is long between Aristotle and Bichat, and Buckle says that he found no middle-man in this long period; it is darker than it is long. During all this time medicine was not taught legitimately. The renaissance, if it may be so called, began with Hunter and Bichat. No real progress,

however, could be made while oxygen remained locked in the silent embrace of all organic and inorganic nature. Priestly, escaping from the religious and political contests, and it may be persecutions, of the old world, came to this country to demonstrate his great phlogiston, oxygen.

Bichat and Hunter restored the proper study of medicine. They represent the turning-point from idealism, speculation and theory, to accurate and close observation. The latter, John Hunter, in 1767, was lecturing and taking students into his own house, and it is curious to know that here, in far off America, Shippen and his contemporaries in Philadelphia and New York, about the same time, or very soon after, began teaching medicine and surgery upon essentially the same plan. Of these men, one who so recently passed away, that you can almost hear the sound of his voice, and feel his magnetic presence, when speaking of the men who lived at the close of the last, and during the early part of this century, said, and justly said, "Not a few of them were the worthy peers of Roux, Abernethy, Crampton, Bell, Graefe, and Scarpa."

To quote again:

"During the past century, medicine has been enfranchised from superstition, *quasi-charlatanism*, bold empiricism and speculation, and has developed into a symmetrical science, affiliated with the other natural sciences, studied by the same methods and by the same appliances as they are, and like them, has been planted upon the solid basis of fact and demonstration."

It may be profitable for us to inquire and determine what part the profession in America has taken, in placing medicine upon the high ground which it occupies. What have we done, what are we doing, and what forecast can we make of the future?

At the close of the eighteenth century, Boerhaave declared that all that had been learned up to that time was comprised in three propositions: "Keep the head cool, the feet warm, the bowels open. All other pages in the volume which he left were blanks. Many pages, however, it will not be denied, have been filled during the present century. What have been our contributions? Have they been such as to rank us with the acknowledged conservators of mankind?

In giving attention to this subject let us for a moment reflect upon the peculiar position of the profession and of medical teaching in this country. For many years (and even now) with few exceptions, medical colleges were the creation of the members of the profession, most often of the faculties composing the schools, without endowment—indeed, it may be said that almost everything on this continent is endowed, except medical colleges—without Governmental aid, depending for their support upon the sacrifice of time and money on the part of the gentlemen occupying

the chairs. Yes, not only without patronage from the Government, but society, from some unknown cause, has ever been against legitimate medicine, depending upon the scientific physician in time of trouble, yet, in the interim, openly supporting all sorts of shams, frauds and impostors.

Elsewhere, college work is provided for by the State; especially laboratory investigations—the nature and the genesis of disease. Hence, it is not strange that, in such departments, we may not be so far advanced as our European brethren; but, while they have been engaged in experimental studies, we have developed the practical. But everywhere is seen among us an earnest, a burning desire for higher culture, for more exact and accurate knowledge. Especially is this true of our younger members and of those about entering the profession.

A movement is being made to concentrate those who have had preliminary advantages—those who enter the profession as college-bred. No objection can be urged to this if it be not too exclusive. All efforts, in fact, to refine our profession without emasculating it, should meet with judicious approval.

#### THE PHYSICIAN OF THE FUTURE.

Whence are medical students to come? What facilities are now afforded, and what does the future promise for the education of our young men, the class from which the medical student, the "coming doctor," is to be selected? The answer to this question will give some comfort, we trust, to the pessimist, and soothe the restless and at times unreasonable critic. And now as to our resources for this work.

By the last census it was shown that nearly four thousand institutions—schools for higher learning—existed in the United States, and that nearly four hundred of them ranked as Colleges or Universities. In these are massed, yearly, sixty thousand pupils. They, together with two hundred thousand common, or primary schools, in the higher grades of which the curriculum nears that of many colleges at home and abroad, a third of a century ago, may be looked upon to supply, year after year, a better material from which medical students will be drafted.

Prof. Charles W. Eliot, in his beautiful and forcible Centennial response, enumerated our educational facilities more generously. He painted our future more hopefully when he spoke of the 8,000,000 children in elementary schools, 250,000 in secondary schools, 60,000 in colleges, with 360,000 teachers to train and develop them.

Every one traveling through the States—especially those of the West and South, and those situated in the far away mountains, and on the Pacific—must be impressed with the onward march of public instruction, the gradually increasing general intelligence, and the vast sums

that are annually expended for the education of the people. Public school buildings, by their size, adaptation and attractive surroundings, give an impression which the most skeptical must feel, a promise of the future which cannot be misread. From such as these, scientific medicine must reap a share. Every teacher, every one connected with the examination of candidates for the medical degree, knows—and the knowledge is reassuring—that, year after year, the grade of the medical student is advancing, that the material out of which the practitioner is made is constantly growing better, becoming stronger; in other words, that the preliminary education of our students is steadily becoming more broad and comprehensive. I gave utterance to this view a few years ago, in an address which I had the honor of delivering to the State Medical Society of Ohio. Time, I believe, has confirmed what I then said. This confirmation is seen in our graduates as they go forth to take up the line and battle of life. Are they not the equals of the graduates in other professions, in law and theology? As life advances, are they not the peers of any, in all the useful elements of true manhood? Are they not the citizens of best rounded characters, citizens most relied upon by their neighbors in foul as well as fair weather?

Again, in addition to facilities already referred to, the most generous provisions are being made, all over our land, for institutions which will be worthy to be called Universities. From these, graduates will emerge worthy to rank by the side of those bearing the prized degrees from Oxford, Cambridge, Paris, Heidelberg or Leipsic.

During the summer of 1888, I witnessed the beginning of a University in California which, in scope and equipment will surpass, probably, any school upon the continent. Should Governor Stanford live to develop his conceptions, that far off State will have an institution of which not only the Pacific Coast, but our entire country; yes, all civilization, will feel justly proud. It may be so liberally endowed that it will command the best abilities of the world.

Of course, upon such an occasion as this, it would hardly be expected that I should in detail refer to the many liberal donations and bequests which have been made, by generous citizens, for developing higher culture—a more comprehensive education. I will, however, be pardoned for referring to a few, and I may say, without being too enthusiastic, that the future is aglow with promise. The high-hearted examples which have been set will be followed by other favorites of fortune, and this country may surpass the world, not only in common schools, but in her institutions for broader and deeper education.

In looking at this promising future, may we not hope that, before another half century closes, students from the old world will flock to this, to

sit at the feet of the wisdom here installed? Is it too much to hope that, in the not far off future, the preliminary education of our students will be equal to that required in the best schools of the world?

Defective as has been much of the material, yet have we not produced some marked results? Our best are equal to the best anywhere; mediocrity always and everywhere finds its own. The poor in medicine, the weak brother, however much we may deplore him, however much we may train him, we have, like the poor, always with us. This is the lot of humanity in all lands, among all peoples, new or old. A word as to the physical qualities of "the coming doctor." Recently a distinguished foreign traveler, in speaking of our educational facilities and national peculiarities, said: "Students are much calmer than their colleagues in Europe. They don't at all trouble themselves about politics or affairs outside their line of duty, and with the practical sense which animates the nation, they try to make the best use of their time. They fight no duels, and it is only for health and recreation that they take part in various sports and games." These remarks apply with equal, in fact, with greater force, to medical students.

It is to the country schools, not to the city-bred, that medicine must look for many of her strong recruits. Cities too often emasculate—young men are vitiated by indulgence and vice before they become possessed of serious thoughts, before they realize the elements of a healthy, vigorous life. It is this country-bred, this excellent material which is, as we have seen, yearly growing better and better qualified to enter upon the duties of the profession. From these we must look for the men of distinction, the leaders of the future.

Is this picture overdrawn? One word more. In many of the States of the Union, in addition to the liberally supported free schools and schools for higher education, already colleges have been established through the munificence of the General Government, in which the degrees of A.B. and A.M. may be obtained. They are absolutely free colleges, at which the poorest boy in the commonwealth may receive a classical education. And here you will allow me to say, we cannot insist too strongly upon the necessity of classical education; without it the medical man must ever be at a disadvantage. Without a knowledge of Latin and Greek, sure and distinguished success is uncertain. The student may neglect Algebra and the Higher Mathematics, but let him, by all means, have a liberal knowledge of languages.

At the last commencement of one of our western schools, "40 per cent. of the graduating class had been admitted on diplomas from literary or scientific colleges. The balance of the class had received from one to five years of academic or collegiate instruction." This college is with-

out endowment—depending entirely upon the learning, devotion and sacrifice of the Faculty.

But to return. Prominent among the States in providing institutions for advanced culture, the great frontier State, Texas claims a high position. The University of Texas will be one of the most liberally endowed; millions of acres of land have been donated for university purposes. There, in that Empire State, may yet be seen one of the greatest schools of literature, science and philosophy on the Western Continent. The University of Virginia, projected in the early days of the century, by her great commoner, Thomas Jefferson, has yearly sent forth graduates equal in all the elements of advanced scholarship to those from any school. This may seem high praise, but the records of her alumni justify me. The same may be said of Harvard, Yale, Princeton, Columbia, Cornell, and of most of our older institutions. The University of California has already an annual revenue of about \$200,000. The Michigan University, with a yearly income of almost a quarter of a million of dollars, has well nigh two thousand students, taught by more than one hundred teachers.

Let us not, gentlemen, be impatient; the influences are already projected which will give us students equal to—up to—the highest standard of preliminary preparation. If we have accomplished so much in our primitive stage, what may we not expect when all our great preparatory works come fully into action?

From this view of the resources from which medical students are to be drawn, and of the liberal preparations and facilities for their culture, we may well ask, what is the profession doing to profit from such advantages?

Some of the classical schools at Oxford and Cambridge were organized as early as the thirteenth century, but the systematic, scientific study of medicine and surgery came long subsequently—not for four hundred years later—about the middle of the eighteenth century. It was first projected in Great Britain, and soon after in our Atlantic cities. Unlike the Old World, our fathers had a wilderness to conquer before progress could be made. When the Pilgrim Fathers left England, reading and writing were rare accomplishments; chimneys in that country had just been invented, and flock beds were luxuries. The adventures—the emigrants to these shores from that ancient and imperfect civilization—had much to learn, but in the midst of their pitiable ignorance, facing great hardness and pressing wants, they were quick to provide educational opportunities for all. The result of their efforts are apparent they are before us. Could more have been accomplished in one century?

#### MEDICAL SCHOOLS.

Our medical colleges now number a few more

than one hundred. They may be classed as: 1, Metropolitan, those in large cities. 2, Medical colleges in less pretentious cities. 3, Medical colleges in small cities. 4, State medical colleges. For convenience, however, we may speak of them as Metropolitan and Provincial.

Before speaking more definitely of our medical institutions, allow me to refer for a moment to the proposition, that medical schools in our country have been developed by the labors, by the self-sacrifice of the profession. As previously stated, it may be said that in this country everything is endowed except medical colleges, schools for teaching medicine. Yes, all financial responsibilities have been and are assumed by the faculties, by men who give every hour not devoted to "earning the guinea" to college work, and in most instances, without pecuniary reward. It is only recently that the wise, the generous, the favorites of fortune, and a few of the States, have conceived the idea of endowing medical schools, institutions where medicine and surgery can be cultivated without the embarrassments of financial responsibility. In the presence of such facts, the work of the grumbler seems indeed ungracious.

In our Metropolitan colleges, every physician may feel a just pride; their graduates, most of them, will compare favorably with those educated anywhere on this earth.

The accomplished Dr. Senn, after a liberal experience with foreign schools, said: "There is no question in my mind, that the average American student learns more in one month, than the average German student in three. He learns more, not because he has better teachers or better facilities, but he makes better use of his time. I am satisfied that in our last graduating class, I had at least a dozen students, who, after studying three years, would pass a brilliant examination in any English or German university. They would have felt at home, even in a dress coat in Volkmann's Klinik passing their final examination."

Provincial schools do praiseworthy, yes, thorough work in training young men, not only in rudimentary branches, but in practical, clinical studies. Many supplement these by hospital attendance in the great cities, and by post-graduate courses. It is gratifying to know that these organizations are being established in all of the great medical centres.

The advance in medical education is again most distinctly pronounced by a remark recently made by one of our distinguished fellows, an American-bred physician, of whose fame we are all justly proud. In a conversation, Dr. Batty said: "When I began the practice thirty years ago, there was scarcely a graduate within fifty miles of my residence; now, however, there is hardly a practitioner in the same territory who is not a graduate, and, year after year, a portion of

our young men leave home to avail themselves of clinical advantages, to attend post-graduate instruction." Could anything show more forcibly the conservative and steady growth of medical culture?

#### HAVE MEDICAL COLLEGES INCREASED TOO RAPIDLY?

Should they be established in small cities where clinical material is limited, where it must be comparatively scarce? Before answering this, it may be well to reflect upon the proposition, that in our own country, as well as elsewhere, great achievements have often been made in the Provinces and not always under the shadow of the Universities. One of the great operations waited for years for a metropolitan disciple—one to take it up—and that too, long after the provinces, at home and abroad, had demonstrated its vital utility, its claim upon the scientific and skillful surgeon.

As our population increased from three to sixty-five millions, the demands for medical men were great—colleges increased necessarily. Have they multiplied in undue proportion?

In answering this question, I beg again to quote from my beloved master, Samuel D. Gross, to whom this question had been put. After mature deliberation, he said: "Our colleges are not annually graduating one physician for each county in the States and Territories. This is certainly not exceeding the demand." A considerable proportion of those who graduate never enter the ranks—death and desertion claim a large share. It would simply be impossible for the metropolitan schools to graduate all required.

For the introduction of young gentlemen into the profession, there is a mutual responsibility between teachers and preceptors. In very truth it may be said that colleges do their duty, their very best, with the students furnished by the preceptors. Give us liberally educated young gentlemen, and we will furnish graduates worthy of the degree. Medical colleges, however, do not make the physician. They merely furnish the foundation work; the individual must do the balance. In no place is evolution so marked—the fittest will and should survive.

#### LABORATORY WORK.

Huxley says: "The microscope extends the realm of Pathological Anatomy to the limits of the invisible world."

"The intimate alliance between morphology and medicine has made the natural history of disease attain a remarkable degree of perfection."

Dr. George M. Sternberg, the distinguished Pathologist, recently connected with the Smithsonian Institution, in referring to some of the laboratories established in this country for the study of Pathogenic Microorganisms, says: "It

is no longer necessary to go abroad for instruction in this department of science, since the Laboratory of Prof. Welsh, in Baltimore, and the Hoagland Laboratory, in Brooklyn, afford facilities which are unsurpassed by any of the laboratories of the old world."

Indeed, it may be said that provisions for the study of Pathogenic Microorganisms are established in most of the leading schools of this country—in New York, Philadelphia, Boston, Baltimore, and the cities of the West and South.

You will pardon me for mentioning some of the investigators.

Johns Hopkins' University has for its Director, Prof. William Welsh. The Hoagland Laboratory, of Brooklyn, New York, established through the generosity of Dr. C. N. Hoagland, has been built and equipped in the most complete manner for research work in Bacteriology and Experimental Pathology. Prof. George M. Sternberg is to be the Director of this advanced institution.

At the University of South Carolina, Dr. Meade Bolton, who has had the best of training at Berlin and Göttingen, is at the head of a laboratory. Dr. H. C. Ernst has the direction of a Bacteriological Laboratory in connection with the Harvard School of Medicine.

Prof. James T. Whitaker, who had the honor of being the first American student of Robert Koch, demonstrated, at Cincinnati, in 1882, the tubercle bacillus, after a lecture upon the subject before the Philadelphia Academy of Medicine. In 1887 the Medical College of Ohio imported a complete outfit for Bacteriologic study. The conductors of the Laboratory, Drs. Rachford, Cameron and Freeman, during the first course, had the opportunity of doing some good work in the discovery of the typhoid bacilli in the reservoir supplied from the Ohio River, then at a very low stage. The discovery led to the general adoption in the city, as advised by leading physicians, of boiling all drinking water, a plan which undoubtedly limited the spread of the disease.

Among others may be mentioned Dr. Prudden, of the College of Physicians and Surgeons, of New York; Dr. Geo. A. Kemp, of Brooklyn; Dr. Mall, of Baltimore; Dr. Booker, of the same city; and Dr. Frank S. Billings, of Lincoln, Nebraska.

One of the earliest, most accomplished and accurate cultivators of microorganisms, is Dr. James E. Reeves, of Chattanooga. His technique is singularly beautiful. Many of his preparations are to be found in the National Museum.

Dr. Victor C. Vaughan and Dr. Heneage Gibbs, conduct laboratory work at Ann Arbor.

The University of Pennsylvania has at the head of its laboratory Dr. John Guiteras, a Pathologist who has distinguished himself in the study of the origin and spread of yellow fever.

Thus it will be seen that in all parts of our

country—East, West, North and South—laboratories are being established for original work.

#### HISTORY OF MEDICAL TEACHING IN THIS COUNTRY.

A brief review of medical teaching in this country will be pardoned—it may be profitable—it will certainly illumine the present, and may be somewhat of interest to the future.

The first medical lectures were delivered by Dr. John Morgan and William Shippen, in 1767, in Philadelphia. Dr. Rush and Dr. Physic soon after participated, and in 1768 the medical department of the University of Pennsylvania was organized; that great school which is steadily advancing to the highest station. Philadelphia was a small, a provincial city at that time; now she is only second to the great metropolis in numerical strength, but second to none in the thorough equipment of her medical schools.

Contemporaneous with Philadelphia, an organization was projected for medical instruction in New York. In 1767, the first steps were taken which resulted in the school, ever since known as the "College of Physicians and Surgeons," one which challenges the confidence of all. The medical colleges of New York, endowed, not by government, but by her public spirited citizens, have won the honors which they wear so well.

In 1785, the first school was organized in Boston. The chairs were four, and the session four months. Harvard is the outgrowth of this humble beginning of that provincial faculty.

In 1800, the first medical instruction was given in Baltimore; since then, the schools of Maryland have occupied a deservedly high position. Recently one of her citizens made an endowment by which the "Johns Hopkins University" will be equipped for the most thorough work, experimental work, laboratory studies, a range and grade of investigations *en report* with the spirit of the times.

This great benefactor has also given to Baltimore one of the most completely equipped hospitals to be found on this earth.

The great Mississippi Valley was yet unknown, but soon after the close of the Revolution, emigration began, and as early as 1799, Dr. Samuel Brown organized the medical department of Transylvania University. Dr. Benjamin Dudley effected a reorganization in 1819. This school, after many prosperous years, having graduated men who acquired distinction at home and abroad was transferred, or rather, most of the faculty removed to Louisville, when and where the University of Louisville was founded.

During the early part of the century, medical schools were organized in several of the Eastern States, usually under State or Church patronage. Most of them exist to-day. Some of the most distinguished men in our profession have been associated with these institutions.

As the West and South were peopled, medical schools were established in cities and promising towns. As early as 1819, Dr. Daniel Drake secured the charter of the Medical College of Ohio, and had it legally connected with the City Hospital. The faculty constituted the hospital staff, the members of which were required to give clinical lectures—the first forward step on the continent, in blending didactic with clinical instruction.

The physicians in South Carolina began medical teaching in 1823, and those of Louisiana in 1835. In both of these States schools of high character have been maintained.

In closing this very brief review of our colleges, Metropolitan and Provincial, I think it may be said that year after year the standard of the Doctorate is being elevated, preliminary examinations and graded courses are being adopted, the smaller schools, to which most blame is attached, whether justly or not, with a disregard of self-interest seldom seen, are yearly reducing the size of their classes by insisting upon higher preliminary education, by extending the curriculum and by graded instruction.

#### MEDICAL JOURNALS.

Medical journals, Metropolitan and Provincial, are the heralds, the vanguards of medical progress, the exponents of professional culture. They are closely associated with the colleges in education and in post graduate instruction. In them appear the best thoughts of the best men; they constitute the great forum of intellectual combat; upon their pages pretension is analyzed and estimated, and worth recognized; that which is new or original is endorsed, or rather encouraged; it is only the plan, the original investigation which is endorsed; the results, the conclusion must be subject to the crucible of test and trial.

The London *Lancet* and the *American Journal of the Medical Sciences* were almost contemporaries—who can overestimate their value—their influence in medical progress. While our journals, both Metropolitan and Provincial, are freighted with the best thoughts of the best men, yet, it must be confessed, that trash and light material—very light material—may be found in all, but the reader, nevertheless, will find much that is not worthless.

THE JOURNAL of this Association has won its way to its present high position by its dignified course and its essentially scientific character; but has it reached its full usefulness? A learned and distinguished author, and a highly prized fellow of our Association, at my suggestion, gives his views upon this question.

Dr. Comegys says: "The undertaking, seven years ago, to establish a weekly journal, was a happy conception, and has been carried on as successfully as the resources of the Association

would admit. To Dr. N. S. Davis unstinted praise is due; proportionate praise is also due the Board of Directors with whom he has been associated.

"A large number of the members believe that it is entirely feasible to enlarge *THE JOURNAL* and give to it increased capacity for usefulness; indeed, that it should be made more fully capable, as the organ of the Association, to assert and maintain the dignity and power of the medical profession as one of the greatest factors in civil life: that to it society must ultimately turn, to find, not only the resource to assuage the distress arising from the diseases and accidents of life, but as to its protection from all those evils that fill the land with apprehension of desolation and ruin.

"We know to what an immense extent we can estop the approach of the pestilences that desolate lands and which menace, through the paths of commerce, the whole area of civilization. We know what we can do to improve the homes and places of labor of the lower and toiling classes of cities and other crowded centres of population. There is nothing, indeed, connected with our own social State, which the medical profession should not supervise and which it should not have the power to control. A great organ is necessary to enlighten, strengthen and lead the profession in all directions to bring, to bear its beneficent agency for the correction of the terrible evils of society.

"Such a journal must be made encyclopædic in character, in which can be found the proceedings of distinguished societies of this country and of Europe, the work of the chief actors of medical progress in all parts of the world. Twelve thousand subscribers would give \$60,000, this would insure \$40,000 from advertisements, making an income of \$100,000, which would sustain one of the grandest journals in the world.

"The *British Medical Journal* in fifteen years has 14,000 subscribers and an income of \$125,000. May we not hope to reach this, and when we do, who can compass the good which the American Medical Association will accomplish."

#### THE MEDICAL AND SURGICAL LIBRARY AND MUSEUM AT WASHINGTON.

Another important factor in professional culture is the great Library and Museum at Washington, evoked by the efforts of an American bred physician, John S. Billings. The Library of the Surgeon-General's office of the army now contains 92,000 volumes, and 137,000 pamphlets, being the largest collection of medical literature in the world, and it is not only the largest, but the most useful. This is because it has an Index Catalogue, which not only shows what the Library has of the works of any author, but for any given subject, indicates all the original articles in journals and transactions, as well as the

books and pamphlets which relate to it, and thus forms a Medical Bibliography which saves an enormous amount of time and labor to those engaged in medical literary research. This catalogue is being published at the rate of one volume a year, nine volumes have been issued, and six more will complete the work. The Army Medical Museum is a great pathological school, and now contains over 15,000 specimens, being one of the eight largest museums in the world, and richer than any other in illustrations of Military Medicine and Surgery. This Library and Museum are national in scope and character. They have at least been securely placed in a fire-proof building well adapted to their needs, thanks to the efforts of the medical profession, and we should see to it that they are maintained and increased to the highest degree of completeness and efficiency.

The Medical Profession asks very little of the General Government, but it does ask that these two institutions shall be made as useful as possible. The number of copies of the Index Catalogue, which Congress authorizes to be published is hardly sufficient to meet the demand, and the repeated requests for authority to publish an illustrated catalogue of the Museum for distribution to the profession have not yet received any attention from Congress, and it is time we took the matter in hand. When we, who are the family physicians of our Senators and Members, say to them that this is a thing that ought to be done and must be done, it is pretty certain that it will be done. There is nothing that will do more to promote higher medical education, to stimulate research, and to crown American Medicine with honor, than to give ample means to this great Library and Museum to obtain materials and to publish widely the results.

#### MEDICAL AND SURGICAL HISTORY OF THE WAR.

This matchless record of Military Medicine and Surgery, is a marked testimony to the profession of our land. Let us for a moment compare it with similar work elsewhere. After the great Crimean war was over, its experiences, collected, weighed and analyzed, how strange in the light of present surgery, and in what contrast with the lessons taught in our great conflict, is the record of McLeod upon one vital operation—trephining for fractures of the skull. In his "Notes on the Surgery of the Crimean War," that distinguished gentleman says:

"If any patients were lost from not having been operated upon, I never saw any of them, but I do know of some patients who died because they were subjected to operation."

And what a fearful commentary upon military surgery of that campaign McLeod makes when he writes:

"Thus it would seem as if severe fatigue,

irregular, and, it might be, intemperate diet, are less injurious to men with fracture of the skull than the probings, pickings and trephinations which form the more orthodox and approved practice."

It may be truly said that the judicious use of trephine during the conflict between the States, supplemented after the war by American surgeons, especially by one of our fellows, Prof. W. T. Briggs, led up, led surely, safely and steadily to the achievements of Victor Horsely, the master of us all in brain surgery.

#### MEDICAL SOCIETIES.

Our medical societies, local and National, are great factors in professional progress. Not alone are they valuable for their social opportunities, but in and through them a vast amount of valuable matter is presented.

#### MEDICAL LITERATURE.

Had Sidney Smith been a physician and given to reading, he would not, even in 1850, have asked the questions: "Who reads an American book?" "What does the world owe to American physicians and surgeons?"

This reverend gentleman, this famous critic, could not have heard of Ephraim McDowell, whose brief paper, detailing his first three cases of ovariectomy, published in "The Philadelphia Repertory," in 1817, was of more value, did more for the conservation of human life than a score of ordinary publications. Our first half-century may be poor in books, but it abounded in strong, brave conscientious and devoted men, men who, with the most limited resources, accomplished the grandest results. They compelled success because they deserved it.

The ink was hardly dry upon that cynical pen when anæsthesia was presented by the profession so poor, as he supposed, in valuable works.

But what country or age can match, in great contributions to the relief of the suffering, McDowell, Sims, Bigelow, Sayre, Batty and Emmett, and that trinity of men—Wells, Morton and Jackson—who gave anæsthesia to the world. Think of anæsthesia and of its influence upon the progress of medicine and surgery. But yesterday a writer in the London *Lancet* gave a graphic history of its reception in London; how the great Liston, having a patient who could not nerve himself up to the point of consenting to have a limb amputated for strumous disease of the knee-joint, decided, that, "if the insensibility could be insured and maintained for one minute, he would amputate." Reflect for a moment on the hesitancy of the great surgeon of University College Hospital, as he stood by the side of that patient; he could hardly believe the novel report as it came over the sea. Willing and anxious as he was to operate, he hesitated to urge the poor pa-

tient to make the experiment—experiment it then was. In a week, however, it was legitimate practice all over the world.

The heart of every American physician is filled with thankfulness when he remembers that in the Providence of God this great boon to humanity was vouchsafed to his country. The very ground upon which stands Massachusetts Hospital is sacred to us all. Associated with the discoverers must ever be the name of Dr. Hayward, who performed the first operation under the strange letheon. Previous to this operative surgery was slow, tedious and almost cruel. Contrast it to-day with what it was previous to 1847. What grand strides it has made under the direct support of anæsthesia and its almost equal co-laborer, antiseptics; the great cavities are invaded, and invaded safely; the abdomen has become a familiar field, and who can forecast the surgery of the brain?

Since Emmett's operation we hear no more, neither in this country nor abroad—neither in London nor Berlin, neither in Paris nor Vienna—of that culmination, that *ultima thule* of ignorance, "ulceration of the os." What a disgrace that term was to the surgery of the world!

The ignorance in diagnosis was only surpassed by the cruel treatment which it evoked, the application of caustics to the tender everted membrane of the cervical canal.

Has the operation, Bigelow's litholapaxy, the crushing and evacuation of a stone at one sitting, been truly estimated? Its adoption in one celebrated case might have changed the destinies of Europe. Previous to Bigelow, lithotritry was an uncertain, and, in most hands, a cruel operation: "Crush all possible at a short sitting, and allow the fragments to pass *via naturalis*." Bigelow realized that if anæsthesia is safe for two minutes, it is safe for two hours or more; hence, he said, "Crush it at once, and evacuate the bladder by an aspirator." The operation, in proper cases, is as practical as the description is brief and efficient.

The accomplished Edmund Owen, M.B., F.R.C.S., upon calculus, says: "With rare exceptions only two operations are now practiced—suprapubic lithotomy and crushing, with evacuation at a single sitting." A high compliment from an eminent authority.

The story of Ephraim McDowell, though so often repeated, humanity never tires of hearing. To us he belongs, and to us only; we cannot share his fame with another; we would not if we could. Who can measure the relief which his operation has bestowed upon suffering woman?—not only woman, for his was the genius which opened the way for laparotomy in both sexes.

#### CLOUDS.

What has been accomplished by the profession in this country, self-reliant, and as we have here-

tofore said, without governmental or social support, is certainly worthy of congratulation, and gives ground for hopes of a rosy-hued future: but, alas! there are some dark clouds to be seen—some spots on our sun of promise! Have we inherent defects in our organic law—our *esprit de corps*?

Upon the face of our promising future some omens of evil appear, indications which look not up but down, not forward but backward, not to the elevation but rather to the degradation of our profession. Heretofore we were an organization into which no species of fraud could enter; pretension, ignorant pretension, stopped at the door. No *ism* or *pathy* was admitted; something more than a diploma, "a legal diploma," was required—a clean bill of conduct, free from false assumption, assumption of universal knowledge, of specific remedies, of imaginary potencies; in fact, of all shams and false claims, a guild in which there was the greatest freedom for the truth, the largest liberty for the right. No vendor of secret remedies was admitted, because of the ignorant presumption in which they were conceived and propagated; but, alas, that we should have fallen upon the evil times when "patented processes" are attempted, when "processes" of valuable remedies are kept secret. These remedies with "patent processes" are in daily use. This is one of the dark spots in the picture. It came in with the "legally qualified practitioner." What is antipyrin, antifebrin, salol, sulfonal? The reliant patient may well propound such questions. Who can answer them? Are we relegated at one fell move back into outer darkness, the associates of vendors of "secret remedies," of "patented processes"? What higher is a "patented process" than a "patented nostrum"? The profession was never so low as to countenance the latter; but have we not, in these latter days, become propagandists of patented and, therefore, secret processes?

#### LAWS FOR THE REGULATION OF THE PRACTICE OF MEDICINE.

It may be asked, has the standard of professional excellence been raised by laws enacted in many of the States for the regulation of the practice of medicine?

These laws banish the poor creatures without diplomas, but make respectable, *quasi*-respectable, all who have so-called diplomas from whatever source. Shams and pretenders are in this way made "legal," and claim whatever protection and recognition that term may give or imply. A chartered institution, in most of the States, represents a formal application for incorporation to a Secretary of State, the signature of that officer, and nothing more. The process of graduating from such—the faculty often consisting of but a single person, or a man and his wife—would hardly be

called a farce; the subject is too serious. "Legally qualified!" think of it; and yet this legally qualified creature will claim and expect to meet the highest and the purest. Is this an advance upon the requirements of the Code, the morals and *esprit de corps* of which have never been questioned?

What has been the effect of these diplomas? Let any candid man answer. Have they not tended to make vice and presumptuous ignorance respectable?

Let us be true to ourselves; pitch cannot be touched without defilement. Our profession must be kept pure or else it will degenerate and sink to the level of a trade.

In State Boards of Health, by the side of physicians, we find these "legally qualified" practitioners. Where lies the responsibility? Is it with us? Our self-examination on this subject should be searching. If we have failed in our duties to humanity, let us be swift to acknowledge it, and be still more eager to correct our error.

The presence of this body of professional gentlemen, representing our entire country, furnishes sufficient argument for the existence of a National Organization; one embracing the virtue and strength of the profession, one to which all questions should be referred for just and final decision. Questions will arise, differences of opinion will occur between honest men. We must have some tribunal, some body, to which these questions, these differences of opinion, can be relegated for solution. The golden rule is a principle, not a law; it cannot interpret itself. Its application to life in detail must be defined. In this respect we are like other men and other organizations. Our *morale*, however, is higher; it has a zeal, a spirit, a hope and confidence peculiarly our own. If we would have our organization pure, we should make it strong—strong enough to eliminate all that is not true or truthful. We are mortals, not transcendentalists. We cannot live as the commune. We must have laws; remembering always that they are not made for the righteous, but for the sinner. "They that be whole need not a physician, but they that are sick." I will not attempt to defend the ethics of our profession. It would be a poor compliment to your intelligence, to your manhood; for there is not a clause in our Code which a gentleman could not cheerfully obey. Organize whatever we may please: Associations of Specialists, of Physicians, of Surgeons; Academies of Physicians; Congresses of Physicians and Surgeons; but let us not lose our loyalty to this parent Association. Projected almost half a century ago, when medical societies were few, it has annually convened—in the North, in the South, in the East, in the West, and in the far West, on the Pacific shore. If you will examine its yearly roster, you will find that it em-

braced the best and the wisest. Almost all who were present at the beginning are at rest; their places have been filled by worthy men. Thus yearly new life—new men being added—this Association can not grow old.

"When a people hold their lives and property as nothing, the enemy has already suffered defeat." So too, when virtue will not compromise with vice, the victory, although it may be long delayed, will surely come.

Of the American Medical Association, let us unite in saying, *esto perpetua*.

## OUR DUTIES AS JOURNALISTS AND THE REFORMS WE SHOULD PER- SISTENTLY ADVOCATE.

*Presidential Address. Delivered before the American Medical  
Editors Association at its annual meeting held at  
New York, N. Y. June 23d, 1887.*

BY WILLIAM C. WILE, A.M., M.D.,

OF DANBURY, CONN.,

EX-VICE-PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION,  
MEMBER OF THE BRITISH MEDICAL ASSOCIATION, EDITOR  
OF THE NEW ENGLAND MEDICAL MONTHLY, ETC

To fill with satisfaction to myself, and with justice to you, the high office bestowed upon me by the Association of American Medical Editors, is a most difficult and embarrassing task. The high rank and standing of the Society, its mighty influence throughout the land, to say nothing of the talent, the brilliancy and the scholarship of its individual members—all seem to demand of me certain special gifts and qualifications which I feel scarcely able to supply.

The most intelligent audience, however, is often the least given to criticism, hence I venture to address you with some slight degree of confidence, yet, at the same time, with a full appreciation of the honor conferred upon me.

It is useless to comment further upon the power which this Association may yield, not only as regards the medical profession of which it forms so important a part, but in other fields, where energy and influence are no less urgently demanded. It remains for me only to indicate the reforms which seem to be most urgently needed, with the full confidence that by the assistance afforded by the medical profession they will be brought to a happy termination.

What then shall be our line of action during the years to come? What changes should be inaugurated? What projects already undertaken should be carried on to completion? These are questions which it becomes us at this time to consider and decide upon. In their treatment, however, we are hampered by the superabundance of facts and suggestions which present themselves, and which by reason of their importance demand special consideration. Let us, however, study those requirements which may be held as essen-

tial to the prosperity and healthful growth of the medical profession.

The subject of medical education as it exists in the country to-day has been often commented upon and held up to criticism. It is a widely recognized fact that year after year there go forth from our colleges hundreds of young men who are totally and manifestly unqualified for the work before them. As candidates for admission, they are, in many cases, unfamiliar with the first principles of English composition, to say nothing of the other primary branches of learning. As graduates they have been found familiar with not one-half of the diseases observed in general practice, much less with the various specialties of medicine. Not only are such men allowed to enter the colleges, but they are solicited and encouraged so to do, by inducements without number, so that no one, of whatever race, nationality or condition, be he moral or immoral, ignorant or well informed, can have any plausible excuse for not studying medicine, and not taking a diploma after receiving two courses of lectures.

For these reasons our system of medical education has become unfavorably known throughout all foreign countries, and such reputation is working us irreparable injury. The present state of civilization demands for our profession not stock companies which derive their revenues wholly from the fees of their students, and which consequently make large pecuniary demands without any adequate returns, but rather, institutions which are able to exercise independence and can, to a certain extent, choose their own students, and can insist upon a four years' study of medicine. There should be three years of clinical work besides such instruction, with frequent examinations by the faculty, and no student should be awarded a diploma who has not a good knowledge of practical anatomy, surgery and obstetrics, as well as a fair clinical acquaintance with the various specialties of medicine. I believe that by proper legislation such a curriculum will be adopted and carried out by every college in the country, while the various mushroom institutions which now exist will be compelled to go into bankruptcy from lack of support.

To bring about such reforms is to excite much hostile feeling and adverse criticism, for both money and influence are pledged for the maintenance of diploma mills, and sympathy is often enlisted even for an unworthy cause; yet with the means at its disposal, it certainly lies in the power of the profession to protect itself and the public as well from the dangers which have been so long in active existence. Recognizing as we do the many shortcomings of the medical colleges and the men they graduate, it seems urgently required that some remedial measure should be at once advocated and put into operation.

We are practically aware of the fact that many of the existing laws governing the practice of medicine are of very limited application, and avail little as regards the suppression of quackery in its various forms, and the protection of the medical profession. Most harmful and disreputable systems of practice are thus allowed to exist and indeed to flourish, and it is difficult and at times impossible to secure the conviction of any one guilty of malpractice. Those who hold diplomas and are now engaged in medical work are, to a great extent, beyond our jurisdiction. It is in the prevention as much as in the treatment of these evils that we are specially concerned. To prohibit the manufacture of ignorant and unscrupulous practitioners, no less than to convict and punish those who already exist, should form our chief aim and purpose.

One of the measures which promises the best results is the establishment of State Boards of Medical Examiners, which might be appointed by the Governor of each State, upon the recommendation of its own medical society. To such bodies should be entrusted the sole licensing power, with the privilege of rejecting all applicants who are found to be notoriously incompetent. Such action has already been taken by at least four States, and in a modified form by five others, all of whom have recognized the fact that it is only in this way that satisfactory results may be attained. We have over one hundred medical colleges in the United States, and the number is steadily increasing. In most there are no preliminary examinations worth mentioning, indeed so great is the competition among the latter that the college which should presume to demand anything but money of the applicant would soon find itself supplanted by the great number who demand nothing at all.

Again, in the various schools of a higher grade there is a disposition to insist upon technical and purely theoretical points, and a disregard of the more practical aspects of medicine. To these various faults and deficiencies there may be applied a like remedy.

State examining boards requiring of the applicant a high standing of scholarship and a thoroughly practical acquaintance with the duties of the profession, would quickly eradicate the worthless institutions, would institute improved methods of instruction, and would enhance the value and the dignity of those medical schools of the first class which are now taking the lead in these measures of reform.

Thus with the increased preliminary requirements an extended and graded college course, with its many improved facilities for instruction, and the final test exercised by an independent examining board, there is an absolute certainty of limiting the number of schools and the number of graduates, and likewise of bringing to the

profession a degree of dignity and status unequalled at any time in its past history.

The policy of protection holds good in the case of medical practitioners as well as in the importation of foreign labor and manufactures. While American physicians are prohibited by the most stringent laws and regulations from practicing in Europe, yet on the other hand, a foreigner with little or no education may come to this country and practice his calling without fear of molestation. The result is a large influx of incompetent and otherwise undesirable men, who come to join the three thousand or more graduates who are turned out yearly by the various medical colleges of this country. The laws governing the practice of medicine in Europe are most stringent and effective, and few, if any, enter the profession there before attaining a fair knowledge of its duties. In Germany, Russia, Switzerland, Italy, Spain, Portugal and other countries, a rigid state examination is demanded. In France the requirements are equally high, while in some parts of Europe the applicant for a license, in addition to his other qualifications, must be a naturalized citizen. In short, we have nothing in this part of the United States at least, which compares in efficacy with the requirements adopted by most other countries. The consequence is we receive upon our shores not only those who have failed to obtain licenses, but also those who have never applied for them; moreover, many of the medical immigrants have little or no knowledge of our institutions or language. They are foreign taught, and know nothing of American methods of treatment. For these latter reasons alone they should be debarred from practice. This state of affairs would, I believe, find an efficient remedy in the supervision exercised by the State Boards of Examiners, who might sit in judgment upon these cases as well, and thereby render their country a valuable service.

While the quack, the pretender, and the incompetent doctors demand, and often receive, fees which are quite out of proportion to the services rendered, the regular physician is too often defrauded of his just dues. In all other professions scientific work demands a more or less adequate compensation, and by virtue of existing safeguards satisfactory returns are generally made for services rendered. In the medical profession, however, there exists comparatively little protection against possible losses. The physician is at the mercy of the dishonest patron, and it is only after a long period of attendance, involving perhaps a great expenditure of physical and mental labor, to say nothing of loss of time, that he becomes aware of the moral and financial standing of his patient, who is oftentimes inclined to depreciate rather than extol the service which he has neglected to pay for.

This state of affairs has existed for years—the

patient going the rounds of the medical faculty and receiving advice and medicine gratis, while the physician suffers in reputation as well as in a pecuniary way. It is time that these acts of dishonesty meet with the punishment which they so richly deserve. During the last few years there has been an effort made in various localities to remedy this evil, and by a plan which has met with success wherever it has been adopted. I would advocate therefore, the establishment in every town and city of a Physicians' Protective Alliance, by which a complete record may be kept of all who are able but unwilling to pay for medical attendance, together with such other facts as occasion requires. With such a method in operation the receipts of the physician would be more in proportion to the amount of labor expended, and his services held in far greater estimation.

There has arisen no question of more vital importance than that which concerns the protection of our country from the invasion of contagious diseases. Yet it is a most singular fact that few civilized nations possess regulations which are so lax and inefficient as ours. Those which now obtain have been inaugurated after long, persistent and laborious effort. Although appropriations have been obtained from the government to be used in the time of need for the suppression of epidemics, yet by reason of the few existing laws and the many restrictions placed around them such sums cannot, and never will enable us to exercise the proper sanitary precautions. Under existing circumstances quarantine is maintained, if maintained at all, by individual States, whose laws possess no uniformity whatever. It has been stated that there are but three ports in this country where proper precautions are in force. The efficient quarantine of one port, however, not only fails at the present time to protect its own State, but really adds to the dangers of the adjoining States, which possess no safeguards. Given one harbor of entry, where infected vessels may repair, the quarantine of all others must necessarily prove of little avail, and it is apparent from this exposed condition of our coasts and the free intercourse existing between the States, we are in constant danger of infection from various sources. An occasional appropriation to be used in cases of emergency, when danger is imminent, fails utterly to meet our wants. At the same time it is not just that individual States, situated on the seaboard, should be compelled to bear the expense of protecting the inland States. Although by means of a large expenditure of money we have thus far protected many of our seaports, still many thousands of dollars have been foolishly wasted, and no permanent or definite results obtained. This applies not only from dangers from foreign sources, but also to those which arise in our midst, and by reason of faulty safe-

guards are allowed to increase and multiply and to extend from one community to another. It is important that the health laws of all towns, cities and States should be clearly defined and identical in their provisions, and at the same time readily executed. It seems wholly improper that the Marine Hospital Service should any longer attempt to carry on any portion of this important work, in fact it would be difficult to determine what special qualifications this department possesses that it should assume an interest in such matters and constitute itself an almoner of the health funds. It certainly has many and important duties of its own, and should therefore be allowed the time necessary for their proper performance. Upon reviewing the question, therefore, from its various standpoints, there appears to be no better way of remedying the numerous evils and shortcomings which exist than the establishment of a National Bureau of Health, which should form a distinct department of our national government, and to which should be entrusted the general supervision and enforcement of all measures relating to sanitation, as well as to coast and inter-State quarantine. The appropriations allowed this Board should be generous, and there should likewise exist a permanent fund which could be drawn upon in sudden emergencies which might arise.

Having secured in this way a general uniformity of all sanitary laws and regulations, with intelligent methods and with abundant means for carrying them into execution, we may expect more brilliant and lasting results than have heretofore been attained. In this Department of Health it would be highly proper that the chief executive officer be made a member of the cabinet as evidence of a proper appreciation of the dignity and importance of one of the most practical branches of human education and knowledge.

That the work of this Board may be carried on with the best results, and in order that there may always be found intelligent aid and coöperation, it is important that the students of all of our colleges should receive instruction in sanitary science. In this latter there has recently been a rapid advance, and in no other department of medicine have greater or more brilliant results been noted.

No specialty can be pursued with better and more definite results than this one, and as the most intractable and fatal diseases seem to be the very ones which are most easily averted, it follows that no practitioner who is unfamiliar with the first principles of this science, can perform his duties with the greatest profit to himself and with justice to his patients. In these matters the physician is, as a rule, wholly self-educated, and in the investigations he may wish to make, labors under disadvantages which a proper preliminary training would have obviated. So urgent, how-

ever, are the present demands of preventive medicine, that we have reason to hope that, with the necessary encouragement on our part, every medical college will be obliged to recognize their importance by establishing a chair of sanitary science, by which students may acquire all of the known facts relating to biology and allied topics, together with the necessary data for future investigations. Said an English writer more than thirty years ago, "Redoubled attention should be devoted to hygiene, both public and private, with a view of preventing disease on a large scale and individually in our sphere of practice. Here the surest and most glorious triumphs of medical practice are to be achieved." The discoveries which have been made and the results which have been attained during the past few years, are but the fulfilment of this prophecy, and should render the student more devoted to sanitary science than ever before.

Facilities for bacteriological work have been heretofore lacking, and American students in this department of science have been obliged to either carry on such investigations under the greatest possible difficulties at home, or to pursue their studies in the various laboratories abroad. Under such conditions we advance slowly and laboriously and can necessarily take little part in the triumphs of modern scientific research. A thorough knowledge of the causes and modes of propagation of disease, as well as the laws governing epidemics, must be acquired before we can use with intelligence whatever resources which may be placed at our disposal. We can now boast of six or seven private bacteriological laboratories, and there is reason to suppose that, if properly equipped and supported, they will do good and efficient work; yet, to meet the many and varied requirements of our Government, something more is needed. Our National health officials should be enabled to carry on the many kinds of investigations needed without assistance from foreign or outside sources, and such experiments should not be allowed to languish or fail through lack of time on the part of the officers or the need of funds to meet current expenses. In no other way can such sanitary work be prosecuted with success, than by the establishment of a bacteriological laboratory, forming an adjunct to the Bureau of Health—liberally maintained by the Government and wholly devoted to the needs and demands of the latter. Many countries have set the example. We have only to commend a measure whose feasibility has been so fully established.

There could be no Association whose interests we hold so greatly at heart, as the one with which we are so intimately connected. Its triumphs and successes are no less our own, while for any failures or shortcomings it might manifest, we should hold ourselves in part responsible. We may then rightfully interest ourselves in those measures by

which the aims of the American Medical Association are defined and furthered, and by which its honors and benefits are rendered free to the profession at large. As the official organ of the Association THE JOURNAL should obtain certain special features. We see too many elaborate and scientific articles, and those which are both uninteresting and far from practical. We are too often obliged to spend too much time in eliminating the great mass of verbiage and dry details with which a few plain facts are surrounded. A journal designed for the general medical reader has no right to fill its columns with articles upon optics, or cerebral localization, or pathological anatomy. Contributions which have their own proper place, should not be inflicted on the general practitioner to be read during the limited time at his disposal. The reports of medical societies may be placed in the same category. If they contain anything of special value let it be summarized and allowed no more space than it deserves. The Association does not require a journal which deals with special branches and investigations, but rather one which will give a comprehensive digest of medical progress and medical news, and at the same time possess such features as will render it popular and attractive.

The editor of such a publication should not be chosen without due care and deliberation, as the office is a most important and responsible one. It follows that, in addition to his other qualifications, he should be a man of liberal education, elevated thought and considerable executive ability. He should be able and willing to devote to the office the care and attention which it demands, without incurring the suspicion of having used it for the purpose of furthering his own private and personal interests. What applies to medical journalism as a whole, may be said to represent the needs and requirements of the official organ of the Association, and the realization of projects for its growth and improvement is, no doubt, a source of care and solicitude to all of us. In this, as in all matters which concern the future growth and prosperity of the American Medical Association, our support and loyalty are pledged. It is within our power to add materially to its usefulness and success, while at the same time we endeavor, by all possible means, to improve the present condition of the medical profession by elevating its standards and placing it upon a firmer moral and intellectual basis.

I have endeavored briefly to direct your attention to some of the more striking evils which now exist, and the measures which might be employed to overcome them. We have, at the present time, an important mission to perform, yet no one who fully appreciates the influence and the capabilities of this Society of Medical Editors, can justly despair of final success. We feel to a certain degree satisfied with the work which has already been

accomplished by our Association, and desire to show our appreciation of the evidences of esteem and encouragement which have been extended, yet no thought is more gratifying to us than the conviction that, in years to come, we shall have been found to have added our full quota to the triumphs and achievements enjoyed by the medical profession of America.

### ADDRESS OF WELCOME.

BY J. H. ELDRIDGE, M.D.,  
OF EAST GREENWICH, R. I.

*The Oldest Member of the Rhode Island Medical Society.*

Having reached that bad eminence—the oldest in fellowship of our State Society—an honor which I share with my friend Dr. Turner, who will address you this evening, the Chairman of our Committee of Arrangements has assigned to me the very pleasant duty of greeting you, gentlemen of the American Medical Association, and giving you a cordial welcome in behalf of the profession of Rhode Island on this, Fortieth Annual Meeting, which you have done us the honor to hold in this State.

It goes without saying, that this is a very small State in point of territory. The most extravagant diminutive can hardly convey an idea of its proportions to those of you who come from without the limits of the New England States. We must also admit that the soil in many parts is barren, rough and unfit for cultivation, and in an agricultural point of view worthless. Nearly half its surface of one thousand square miles is in its primitive state of forest or brush-wood; and another large portion is covered by the waters of the bay.

With all this, which we ourselves see and must of necessity admit, and which must be apparent to the casual visitor, we have much in which we take a laudable pride. What nature has denied to us in some ways she has been lavish of in others. We are proud of the illustrious founder of our State and the inheritance of civil and religious liberty which we have received from him. We are proud of our historic record from the first settlement of the State, through all the wars, down to the present time, and of the heroic names which are associated with us and which belong to us. We are proud of this lovely city by the sea, of which so much will be told you by the gentlemen associated with me. We are especially proud of our Bay with its numerous indentations, islands, and headlands sloping everywhere green and fresh to the water's edge. We value very highly the great extent of shore bordering our tide-waters, measured by hundreds of miles, upon which we, the present natives, taught by the aborigines, have learned to depend for our chief supply of food, never failing, all seasons alike, the delicious bivalve of every kind everywhere abounding.

No visitor is permitted to leave this State until he shall have tasted this healthful, delicious food prepared in the primitive Indian way.

This shore privilege, as it is called, is an important feature in our Bill of Rights. All below high-water is public property. If in your efforts to reach this public domain by the nearest route, you should commit a trespass by crossing some private grounds, you may be assured you will only be mulcted in nominal damages—if the trial is before a jury, especially a Kent County jury.

We take an especial pride in our institutions of learning. Our Brown University, our Free Public School system, our Free Public Libraries, in every town—recognized and partly supported by the State, and everywhere doing a good work—continuing and completing what the free school has begun. Nowhere can all this be seen in better condition, more successful operation, than in this good town of Newport.

In our industrial enterprises, to which we are indebted for our prosperity and wealth, our cotton mills, our foundries and machine shops, where you can see the natural fibre—wool or cotton—wrought into the finished fabric; where you can see the construction of the most powerful stationary or locomotive engines and machinery of every kind.

Notwithstanding the poverty of the soil and the rough, rocky surface which so generally prevails, we have some specimens of fancy farming and fancy breeding; and also planting of forest and fruit trees, which plainly show what we might have done if we had earlier turned our attention to these important matters.

All this, and more which I might speak of, is so convenient, so accessible by land or water on either side of the bay, that, in the *hora subsequa*, from the more important affairs for which you are assembled here, you will find abundant opportunity to visit and examine for yourselves.

Among the original settlers and founders of this State were a goodly number of physicians, or surgeons, as they were then more commonly called. Dr. Turner will give you a very full historic sketch of the most prominent of these men in the Rhode Island settlement. Other men of the same stamp, maintaining the same position in the Providence plantations, were associated with them. The respect and consideration which these good men could claim, and which was everywhere granted to them, has been transmitted through many generations of worthy successors, until we of this day are enjoying the goodly fruits thereof.

You have then but to announce yourselves as physicians, as members of this convention, as visitors, delegates from other States or other countries, to find everything opened for your inspection, and to be received everywhere with a cordial welcome.

## ADDRESS ON SURGERY.

*Delivered at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June 27, 1889.*

BY PHINEAS S. CONNER, M.D.,  
OF CINCINNATI, O.

The surgery of the century has been of three periods: the preanæsthetic, the anæsthetic and the modern one. Operative brilliancy characterized the first. The suffering inseparably connected with the use of the knife and the nervous depression resulting therefrom was to be limited chiefly by celerity of execution; hence, the swift moving hand was an essential part of the equipment of the fittest surgeon.

When, in the amphitheatre of the Massachusetts General Hospital, "the problem of surgical anæsthesia was definitively solved," a new period began. Pain was no more, and it was permitted to examine earlier and more thoroughly, to remove more extensively, and to operate successfully in regions previously altogether, or in great measure, beyond the reach of art. For twenty years or more, progress was in the line of diagnosis, of development of new and better methods of operating, of extension of the range of surgical interference. Time was no longer an element of prime importance, and the work was regarded as quickly enough done when well and thoroughly done—too much so, in fact, for not seldom the best interests of the patient have been jeopardized by unnecessary delay in execution, that would not have occurred but for the existing profound insensibility. But though operations in this anæsthetic period were without much of the terrors of the olden time, they yet fell far short of producing the wished for result in preservation of life and early restoration to health. Wound complications were still as ever the bane of surgery, and too often the wisest planned and best executed operation resulted in failure because of the supervision of one form or other of septic infection.

It is scarcely twenty years since patient investigation, careful experimentation and practical testing began to throw strong clear light upon that most obscure of the subjects of medical study, the causes of disease. As never before in the history of medicine, truly scientific methods of research have been adopted and pursued by a multitude of trained observers in all civilized countries, and surgery has entered upon its scientific period, in which operator and patient are profiting by the labors of the chemist, the botanist, the physiologist, the physician, equally with those of the practical and experimental surgeon. It seems but yesterday when Lister's early papers startled the world. It is but twenty-two years since the first one was published, yet what enormous advances since then in knowledge, in treatment, and in the field of operative interference. A new department of science, surgical bacteriology, has been created (for what was done prior to

1867 may for practical purposes be left out of consideration), and in its development has been worked out the mycotic origin of all those pathological processes looked upon as inseparable from traumatism, or almost necessarily associated with them if severe. Suppurations, gangrene, septic infection, erysipelas, tetanus, we know to depend upon the presence or the action of one or other of definite organisms that may be isolated, cultivated and inoculated. Recognizing the cause, it has been comparatively easy to devise methods, more or less perfect in action, to prevent the development or neutralize the influence of it, and there has been worked out an antiseptic and aseptic wound treatment, the results of which are simply marvelous. But just here I must protest against the wisdom or the justice of the sweeping declarations of a few enthusiasts, who see in other than speedy recovery after injury or operation evidences of what they are pleased to consider criminal ignorance or neglect.

The existing strong probability that in any given case septic infection might be prevented, has given warrant for the performance of operations that in preaseptic days were not to be thought of.

Abdominal surgery, that so short a time ago meant scarcely more than the removal of an ovarian tumor too often carried until death was evidently fast approaching, now includes operations upon almost every part of each hollow and solid viscus, and laparotomy has taken its place as a safe, proper, and often indispensable prerequisite to the determination of obscure diseases. Penetrating and perforating gunshot wounds, so generally fatal when treated by rest and opium, have in at least forty cases been recovered from after section and suture, and there are now but few surgeons still unconvinced of the wisdom of early active interference. At our last meeting Senn's carefully elaborated and beautiful demonstrations set forth a means of determining the existence and location of intestinal wounds that if safe, as it has thus far seemed to be, will remove the greatest objection to laparotomy in these cases, the uncertainty in the earlier hours of bowel perforation—and prevent what otherwise will occur, the overlooking of one or more lesions. It is not to be expected that all or any close approximation to all of these very dangerous wounds will be saved by early operation, for great injury will ordinarily be produced by the bullet, be it large or small; but every case that recovers after section and suture may fairly be considered as rescued from an otherwise almost inevitable death. Unquestionably the laying open of the peritoneum and operating upon an abdominal organ has at times been carried too far. Useless work has been performed, and life has been sacrificed, for it is not true (so far certainly as operators in general are concerned) that abdominal section is in itself

without danger, doing no harm if it accomplishes no good. But not a day goes by that somewhere or other life is not prolonged and comfort secured by an intraperitoneal ligation, suture, anastomosis or excision, rendered proper, may we not say possible, only by the aseptic results of scientific discovery and experimentation.

So, too, the diseases and injuries of the other great cavities are being attacked by the surgeon's knife guided by the diagnostic knowledge, the localizing exactness and the technical skill of the physician, the physiologist and the vivisector.

There has been but a beginning of intrathoracic surgery, though for years empyemas have been treated by free incisions, supplemented not seldom by extensive excisions of portions of the chest wall, and even in preaseptic days deeply lodged foreign bodies were removed. Only very recently has the lung been cut into for the evacuation of abscesses and the treatment of gangrenous areas, such pneumonotomies resulting favorably in one-half of the reported cases; and as yet but few subpleural tumors have been attacked. There is every reason for believing that in the near future surgery will be able to render great service to the subjects of not a few forms of thoracic disease now regarded as beyond the reach of art.

The most recent and the most brilliant triumphs have been in the treatment of diseases and injuries of the brain and cord. Nowhere else have our art and science so joined hands in affording relief as here. Tumors removed, foreign bodies taken away and their tracks drained, convulsion-centres excised, serous effusions tapped, life preserved and comfort secured; so reads the record. Much remains to be done in the determination of the trouble, the exact localization of the mischief, the perfection of technique. Not seldom mistakes will be made, errors committed; but it will be more and more demonstrated that the trained mind and the skilful hand, working together, can recognize and successfully treat otherwise irremediable affections within the skull and the spinal column.

As the operative procedures necessary for the exposure and removal of the spinous processes and laminae of the vertebrae are but little dangerous, and as septic meningitis can almost certainly be prevented, a change may reasonably be looked for in the treatment of vertebral fractures, especially those in the lower half of the column. Up to this time the cases in which active interference has been made have almost always been those of long duration, in which existing inflammatory changes in the cord, if nothing worse, could not but prevent any favorable result; but even in these, of late, the patient has been none the worse for the operation. Without doubt, early removal of pressure, whether made by bone or blood it matters not, would save many an one from all those deplorable conditions consequent upon my-

elitis with which we are unfortunately too familiar.

Is there any good reason why spine fractures should not be treated as skull fractures? and who would now for a moment think of rest and position as the routine treatment of the latter injuries?

But in this scientific period there has been much more accomplished than extension of the range of operative interference, great and important as this has been. As never before it has been possible to preserve damaged parts and to retain important functions, to replace completely detached pieces of bone and secure adhesion as perfect as of the fragments in a simple fracture, to transfer large areas of integument and ingraft pieces of bone, to supply deficiencies in soft or hard parts by skin or bone from dog, rabbit, chicken or frog. Every department of conservative surgery has been and will yet more be benefited by the preventing of the evils consequent upon the action of minute organisms.

The two diseases that produce the widest destruction to part and to life are tuberculosis and cancer. The former, that until the discovery of its causative bacillus was regarded as of rare occurrence in parts belonging to the domain of surgery, is now known to be the producer of the vast proportion of the diseases of bones and joints, and of many of those attacking the skin and more external organs.

Primarily and often for a long time local, if allowed to go on unchecked, it effects other and remote regions, perhaps rapidly becoming generalized. But what has been learned respecting it—that it may attack any part the blood circulation in which is disturbed by general enfeeblement or local injury of ordinarily not severe character; that the bacilli may be destroyed or become encapsulated; that the softened tissues may, in like manner, be taken up and carried off or shut in temporarily or permanently; that if the diseased focus be completely removed, as it often may, the part and the whole are as if it had never existed, except so far as function is disturbed by the loss of what has been taken away, and by the scar tissue resulting? How has treatment been affected by this knowledge? It is of prime importance that early diagnosis be made. Located in bone or joint and detected while yet limited, prolonged rest, as absolute as possible, will in the majority of cases, certainly in young subjects, secure destruction, absorption or encapsulation of organisms or affected cells with resulting restoration to health. Advanced to the stage of caseation and liquefaction, rest may yet be followed by recovery, though ordinarily free drainage, with or without associated removal of the infected tissue, will be of great advantage. Injection of agents such as iodoform or the acid phosphate of lime, that will destroy the bacilli and the tuberculous masses, may produce the wished for cure. But ordinarily it will be better, indeed generally

necessary, to remove the affected area either by formal or informal excision or by amputation. Whether diseased joints are best treated by arthroctomies or by typical excisions is one of the questions still *sub judice*, though in the last three years, as never before, it has been shown that formal removals of the larger articulations can, in a large proportion of cases, be followed by early repair and solidification without suppuration or constitutional disturbance; even at times with recovery of original function. Though it is not likely that it can ever be said with truth that the days of the lame and the hump-backed have gone by, because of neglect, delay, or generalization of the pathological process, yet we have good reason to believe that further advances in knowledge of the development and extension of the tuberculous disease will enable the surgeons of the future to so limit, ameliorate and cure the surgical tuberculous affections, as that they will no longer constitute one of the most important and destructive of the external diseases.

Of cancer it may with truth be said we know very little; yet of nothing do we more need knowledge. Much less often met with than tuberculous disease, it is yet of not infrequent occurrence. In our eight largest cities (Boston, New York, Brooklyn, Philadelphia, Baltimore, Chicago, St. Louis, and Cincinnati) during the five years ending Dec. 31, 1888, of 599,684 deaths from all causes 13,094 were from cancer, 2.18 per cent., and as we all know the disease is not peculiarly an urban one. In five of the eight cities, New York, Chicago, Cincinnati, Brooklyn and St. Louis, the death rate was much the same, being in the order given 2.1, 2, 2, 1.94, 1.93 per cent. In Boston it was highest, being 2.98 per cent.; in Baltimore it was 2.4 per cent., and in Philadelphia 2.28 per cent. In Cincinnati in the last year the percentage reached 2.6 per cent., while in 1868 it was but 0.55; an altogether exceptional rate, however, as only once since has it fallen below 1 per cent., in 1870, when it was 0.8. For these figures I am indebted to the health officer, Dr. Stanton. One in fifty then of the deaths in an aggregate city population of over five millions is due to this disease, and if we have regard only to the mortality of those within the cancer age, *i.e.*, more than 35 years old, about one in twenty of the deaths is thus produced. Even among the carefully selected adult individuals carrying life insurance, who are free or are supposed to be, from family predisposition to cancer, from 2.5 to 3.5 per cent. of the mortality is from this disease. The statistics just mentioned and, particularly the marked contrast between the high death rate in Boston and the low one in St. Louis, gave but little support to the theory of Haviland, that low lying lands subject to frequent overflows are those in which the disease is most prevalent.

In preparing the mortality statistics of the census of 1880, Dr. Billings found that the disease was most prevalent in New England and Southern California, and least so in the South and upon the Mississippi. It is to be hoped that in the preparation of the vital statistics of the next census such attention may be given to this subject of occurrence and distribution, and such full and complete reports secured as will add materially to our knowledge, and go far towards determining to the correctness or incorrectness of the views of the English writer named. Care should be taken to separate, if possible, cases of sarcoma from those of cancer.

Hirsch to the contrary notwithstanding, this affection is becoming more common throughout the civilized world, certainly is so in our own country and in Great Britain. Increased accuracy of diagnosis will not account for a doubling in twenty years of its mortality rate in Massachusetts or in Cincinnati, or in less than twice twenty years in England. Frequently, if not usually, attacking individuals in good general health (though oftentimes appearing soon after a period of marked mental anxiety and depression), it has regard neither to social conditions nor hygienic surroundings. Unlike consumption, which is often of limited duration ending in recovery and at the worst, ordinarily bringing death gently, cancer left to itself very rarely is spontaneously eliminated, is almost inevitably destructive to part and to life, and is often attended with severe physical and mental suffering.

What is its starting point. An unused long-dormant embryonic cell, at length aroused to activity by local irritation, general enfeeblement or nervous exhaustion? In all probability, no. An abnormal epithelial development, abnormal because unconfined within its normal limits? But why unconfined. An epithelial cell undergoing proper degenerative changes, but arrested at some point short of its complete alteration? What stops its retrograde movement. Is it of mycotic origin? That it should be so would hardly be more strange than that lupus or lepra should be. That it is so has not yet been proved. The many investigations that have been made, some of them for a time apparently fruitful, have thus far failed to discover a causative bacillus, unless further and extended cultivations and inoculations shall prove that Kubasoff has actually found it. Experimental inoculations have again and again produced no specific result, but Lampiasi has claimed that by using a bacillus culture from the blood he succeeded in causing in a healthy part of the patient's skin the growth of a nodule having "an alveolar stroma with wide meshes, which contained many epithelial cells of different form and sizes;" and Hanan has twice successfully transplanted from rat to rat.

No more inviting field is open to the bacteri-

ologists and experimenters of our country (and we have a number of them, as also well equipped laboratories), than this very one of cancer. Cases are numerous, specimens are being daily secured, and there is no reason why America should not now do full part in settling the vexed questions of nature and origin. The imperative necessities of a struggle for existence, and the intense practicality of a new and developing country have heretofore prevented any but the very few filled with enthusiasm or independent of fortune from engaging in purely scientific studies involving minute investigation and patient labor with often no apparent practical outcome. But the times are changing, and the profession of our country may, and doubtless will ere long be as well and favorably known in biological research as it has been, and is in relation to ovariectomy, to ether, to the hip, to the treatment of stone, to the surgical diseases of women, to abdominal section, to a multitude of affections, and the means of treating them.

As we see it in lip or breast, or uterus or stomach, or it matters not what part or organ, is cancer a local disease, or but a local manifestation of a constitutional state? The question is still an open one, though the great majority of pathologists and clinicians are now agreed that wherever seated it is primarily, and for a time purely local, whatever may be the general conditions inherited or acquired that permit or favor its development. If not of limited area and capable of complete removal, operative interference can be justified only on the ground of affording temporary relief—unfortunately all that is accomplished in the majority of cases submitted to the knife. But there is great encouragement in the knowledge that a certain percentage of patients operated upon do recover; that is remain free from recurrence for three or more years; and that this percentage is larger or smaller, according as the disease is so situated as to be early detected and thoroughly removed, or the contrary. Located in the lower lip or the cervix uteri, for example, two out of five patients operated upon get well, in the breast one in eight. Why this great difference. Because, we may believe, of the site itself and of the degree and rapidity of extension, in parts immediately adjacent and of glandular involvement; in other words, of the likelihood of early and the possibility of complete extirpation, or the opposite. How are to be regarded those cases in which after five, ten or twenty years of apparently perfect health, the disease again shows itself and destroys life? As of long quiescence of infected and infecting cells or of a new and independent affection. The latter explanation certainly makes a far less demand upon our credulity, and it is no more strange that there should be a second than a first attack in a person and tissues possessing and undetermined and

unknown receptivity, and such there certainly must be that cancer may be developed at all.

Of nothing are we more certain than of the immense advantage there is in early recognition and speedy removal; and, on the other hand, of the utter uselessness, so far at least as the ultimate result is concerned, of any surgical interference after a wide extension has taken place.

In perfecting, therefore, the means of establishing diagnosis at an early day lies an important work in the future. Though consideration of age, of location, of pre-existing long-continued irritation, go far towards settling the nature of a given tumor, and upon such estimation of probabilities action may generally be safely taken, yet, as a rule, certainty of the character of the growth can only be had after scientific determination of its anatomical constitution. Whatever then makes it possible to safely, easily and without pain remove for microscopic examination, a sufficiently extensive piece of the mass to show its deep as well as superficial structure is of much practical value. A convenient and promising little instrument has lately been given to the profession by Dr. Collins Warren, of Boston.

Physiological and chemical investigations have furnished us with early and reliable evidence of the existence of cancer of the stomach in absence of the hydrochloric acid from the secretions of that viscus; may not kindred investigations give us like aid when other organs are affected?

The modern and scientific wound treatment now enables the surgeon to remove more extensively and at the same time safely, so that active interference may reasonably be expected to be, and is attended with much better results, than could be looked for a few years ago. Much of the work, though that in the last decade has been done upon internal cancers, has been of questionable utility; chiefly because of its late performance.

What will the future reveal respecting the non-operative treatment? Will a drug or drugs be found to secure destruction and removal of the morbid mass? May the moderate continued electric current or powerful interrupted currents "flashed through" prove to produce as has been claimed for them, entire disappearance of the diseased cells? Can some pathogenic organism be inoculated that without killing the patient will break down the malignant growth? We all know what has been done with the micrococcus of erysipelas.

In nothing could this Association do more than in determining by collective investigation and thorough committee work the frequency of occurrence of carcinoma in the country as a whole, and in its several States, the relation borne (if any) to geological formation, the age of appearance, the relative affection of parts and organs, the influence of therapeutic treatment, and the duration of

life with and without operation. Five years of such work would suffice to accumulate a mass of statistics of very great value, the study of which could not but advance the best interests of patients and practitioners; and in this, as in everything else "many hands make light work." To physicians, surgeons and therapeutists, the subject is one of prime importance, and only by combined scientific and practical work can it be determined what excites and produces the disease, and what can secure its relief.

As we survey the advances, etiological, diagnostic and therapeutic, made in the few years just past, that are of the scientific period, and consider, even in the most hurried way, the problems that are yet awaiting solution, problems relating to nature, origin and treatment of the diseases and injuries of parts within the domain of surgery, what may we not reasonably anticipate as the future of our science and art. Accidents must occur, diseases will prevail, no matter how great the triumphs of preventive medicine. Surgical pathology is but in its infancy. Years ago it was declared that operative surgery had reached its climax. Yet, since then, operations have over and again been done within abdomen, chest, and skull, upon the larynx, throat and spinal cord that in boldness of conception and brilliancy of execution have no parallel in the history of medicine. The end is not yet, nor will it be while, the world over, there are active minds and cunning hands busied with the determination of the existence and extent of surgical affections, and ready and able to remove them, aided more and more by the labors of investigators in many departments of science, general as well as medical. Year by year, he who may deliver the Address on Surgery will be able to report doubts removed, discoveries made, remedies employed and operations done.

#### ADDRESS OF THE CHAIRMAN OF THE SECTION ON THE PRACTICE OF MEDICINE, MATERIA MED- ICA AND PHYSIOLOGY.

*Delivered at the Fortieth Annual Meeting of the American  
Medical Association, June 25, 1889.*

BY FREDERICK C. SHATTUCK, M.D.,  
OF BOSTON.

In obedience to the rule of the Association that the Chairman of each Section shall review the progress which the year has brought in those subjects which immediately concern his Section, I ask your attention to a very brief consideration of a few of the large number of topics which might worthily find notice here.

The practice of medicine, materia medica and physiology include so much, the workers are so many, and the fruits of their labors are so varied

and abundant that the difficulty of selection is itself an embarrassment.

The grass had scarcely grown on the grave of the treatment of pulmonary tuberculosis by gaseous enemata before another curative method was advocated by Weigert<sup>1</sup>, Halter<sup>2</sup>, and Krull;<sup>3</sup> a method which would seem at first sight to have claims to be called curative in that it is designed to remove the cause of the disease by destroying the bacilli *in situ*. We know that the development of this particular microbe is arrested at a temperature of 107° F.; and if, then, the intra-pulmonary temperature can be raised to or above this point and there maintained for a time the happiest results must follow. I can confirm the statements of the originators of this method as to the ability of patients to breathe with impunity air at a surprisingly high temperature. I have myself inhaled it at 320° F., and seen patients inhale it at 428° F., without notable inconvenience. Nearly six months ago Dr. G. G. Sears, of Boston, began to practice inhalations of hot air on some of my patients in the House of the Good Samaritan. His results are now ready for publication, and it will suffice to say here that an apparatus was used devised by Mr. G. L. Kingsley, of the Harvard Medical School, an apparatus which can be made by any coppersmith for \$5—that patented by Weigert costs in this country \$75—and that we are satisfied that the problem of intra-pulmonary direct germicidal action is still unsolved.

The pancreas, an organ the diseases of which have been until recently of pathological rather than clinical interest, is being dragged from obscurity. Senn's work on cysts of the pancreas is followed up by Fitz,<sup>4</sup> who has collected 70 cases of the several forms of acute inflammation of the organ and subjected them to a rigid analysis, which yields a notable increase to our knowledge. A frequent cause of acute pancreatitis seems to be the extension of an inflammation from the duodenum into the pancreatic duct and thence to the interstitial tissue of the organ; which tissue stands in such relation to the peritoneum, the retroperitoneal and retropancreatic fat tissues, as to permit the ready passage of bacteria, and thus account for the peritonitis and disseminated fat necrosis so often resulting from pancreatic inflammation. Inflammation of this organ is doubtless much more common than has hitherto been generally supposed, and is not impossible of diagnosis. The affections with which it is most likely to be confounded, are, irritant poisoning, perforating gastric or duodenal ulcer, perforation from gall-stones, and acute intestinal obstruction. The first three can be excluded by the history of the case

<sup>1</sup> N. Y. Med. Record, 1883, ii, p. 693.

<sup>4</sup> The Middleton G. Adsmith Lecture for 1887. Boston Med. and Surg. Journal, 1889, pp. 181, 203 and 229.

and the associated symptoms; the last by determining the potency of the large intestine through injection, by the seat of pain and tenderness of the upper abdomen, and by the absence of marked tympanites. I trust that I may be pardoned here for bringing in my own personal experience, which I do with the less hesitation, inasmuch as it is not especially to my credit. It was my lot during the past winter to be one of six physicians and surgeons at a consultation; four of us considered the case as probably acute intestinal obstruction, one inclined to perforation, while Dr. Fitz alone held that it was acute pancreatitis, and advised against operation. Laparotomy was done, no obstruction was found, and multiple fat necrosis was seen in the omentum, and the autopsy revealed acute hæmorrhagic pancreatitis.

Frerichs<sup>6</sup> long ago noticed the frequency of atrophy of the pancreas in diabetes mellitus; and Lancreaux in a recent and important paper calls attention to the relation between these conditions, based on 20 cases which he has seen, with post-mortem verification in 14 of these. Pancreatic diabetes, in contradistinction from the other forms of the affection, is characterized by sudden onset, rapid course, and severity of the symptoms, with great emaciation. In two of the cases, by the way, epigastric colic lead to the diagnosis of pancreatic calculus, and the autopsies brought justification.

Here we may allude to the experiments of Pavloff and Smirnoff,<sup>7</sup> which show that in rabbits, whose pancreatic ducts have been ligated, regeneration of the gland may take place after a new and spontaneous communication with the intestine has been formed.

The much vexed question as to the nature of diabetic coma, with the indications for the liability of its occurrence in any particular case, and the means for its relief are ably considered by Kirstein,<sup>8</sup> who details the steps through which our present knowledge has been attained. In certain cases of diabetes the organism seems to have lost the power of burning the fatty acids, largely  $\beta$ -oxy-butyric acid, to their normal end products. These cases are characterized by a large increase in the amount of ammonia in the urine, rather than by any striking symptoms or complex of symptoms, and these are the cases in which coma is to be dreaded; this form of coma being the result of the formation of larger amounts of free acid than can be neutralized by the ammonia which the organism is capable of supplying, the consequent abstraction from the blood of the fixed alkalies, and thus toxæmia.

The quantitative estimation of ammonia in the urine of diabetics is consequently of great importance therapeutically as well as for prognosis; but

unfortunately a method for this estimation readily applicable to clinical purposes, is still lacking. When this large excess of ammonia is found the indications are to restrict the acid—rather than the sugar-forming foods, meats for instance—and to give alkalies freely. On the advent of the peculiar dyspnœa, which is apt to be the first symptom of coma, alkaline intravenous injection is to be practiced, as has already been done in a small number of cases, Minkowski alone having saved his patient.

The diseases of the blood have been studied by Graeber, Hunter, and others. According to Graeber<sup>9</sup> anæmia, chlorosis and pernicious anæmia are distinguishable from one another by a count of the red corpuscles and a hæmoglobin estimation. Hunter<sup>10</sup> argues to show that pernicious anæmia is an entity, pathological and clinical; depends on increased blood destruction, probably in the liver; and is to be differentiated from all grave anæmias, as, for instance, those of cancer and intestinal parasites, as well as from all other primary anæmias, by the greatly increased amount of blood pigment, responding to the micro-chemical tests for iron, found in the liver in this affection. The spleen contains no such excess of iron as does the liver; and, in the latter organ, the seat of the pigment is chiefly the outer portions and cells of the lobules, not the capillaries, a fact which goes to show that the blood destruction takes place in the liver itself, the pigment entering the cells in soluble form—hæmoglobin—and there undergoing conversion into albuminate of iron. In all cases where the blood destruction takes place elsewhere than in the liver, and pigment is deposited in that organ, it accumulates in and about the capillaries.

A paper of MacMunn,<sup>11</sup> of Wolverhampton, on Addison's disease is noteworthy. He has studied the adrenals and urine of patients with this disease, spectroscopically; and, reviewing our knowledge of the subject, concludes that the function of the adrenal bodies is the removal from the circulation of worn-out pigments and their accompanying proteids. "When the adrenals are diseased these effete pigments and effete proteids circulate in the blood; the former, or their incomplete metabolites, producing pigmentation of the skin and mucous membrane, and appearing often in the urine as urohæmatoporphyrin; the latter producing tonic effects, and leading to further deterioration of the blood with its consequences."

At our meeting in Cincinnati, last year, a discussion took place on the modern method of diagnosis of diseases of the stomach; and high hopes were expressed that by the examination of the gastric contents, an ease and certainty of diagnosis in these affections is almost within our reach

comparable to that which urinary analysis yields in renal diseases. The more carefully the question is studied, the greater is the demand for yet further study, and the more clearly does the necessity appear for the exercise of great caution in the formation of definite conclusions at present. In the first place, it is now seen that the only single test for free hydrochloric acid which has a real clinical value, is the phloroglucin-vanillin; the tropæolin, congo red, methyl violet, and other tests, either reacting to other acids or acid salts, or being often prevented from reacting by albuminoids, even when free hydrochloric acid is present. Secondly, it gradually appears that it is not safe to base a diagnosis of gastric cancer on even the persistent absence of this acid from the gastric contents withdrawn an hour after a test meal. Such absence is indicative of notable impairment of the functional activity of the mucous membrane, as from a severe catarrhal condition; or of extensive destruction of the secretory glands of the stomach, largely irrespective of the cause of the destruction. Thus, in a case of cancer sharply localized and unaccompanied by catarrh to any marked degree, free hydrochloric acid may be found in sufficient amount until the cachexia is well advanced. On the other hand, in severe but simple catarrh, especially if attended by the formation of much mucus; in atrophy of the gastric tubules; in amyloid disease of the organ; after strong caustics have done their work; even in certain cases of impaired innervation; no free hydrochloric acid may be detected, though sought for repeatedly with the utmost skill and the aid of every appliance and reagent.

It also appears that hyperacidity though a frequent, is by no means a constant accompaniment of peptic ulcer.

Indeed it is impressed upon us that the pathology of an organ which varies so widely physiologically in the same individual within such short periods of time is a very complicated thing and the lesson is again enforced that it is not in pathognomonic signs, but in careful weighing of each piece of evidence and in the painstaking collocation of them all that accurate diagnosis is to be attained. Before leaving this subject I must say a word in praise of Ewald's remarkable work on *Diseases of the Stomach*,<sup>11</sup> and of the balance which he preserves while enthusiastically pursuing his subject.

During the past year the internal antipyretics have continued to seek their level. It is seen that they exert no curative influence on specific febrile processes; and, as we recognize more and more clearly that even continued fever is not productive of the changes in the parenchymatous organs with which we credited it of late years, but that the danger in these processes lies rather in the effects of toxic alkaloids on the nervous centers

than in temperature elevation, as we recognize this fact, we appreciate how irrational it is to address our therapeutics chiefly to pyrexia. When the fever is in itself productive of discomfort to the patient the internal antipyretics are useful; but the indications seem to me, at least, strong that the antineuralgic and analgesic will survive the antipyretic application of this class of drugs.

On the other hand, it seems probable that the cold-bath treatment, if continued, and especially of typhoid fever, must be adopted and conscientiously carried out in this country. As the principles of Brand's methods gain headway in France, a country not prejudiced in favor of German leadership, as Brand's results are confirmed by other observers, and in other countries, and in the face of such statistics as are put into our language by H. C. Wood,<sup>12</sup> Wilson,<sup>13</sup> and Baruch,<sup>14</sup> it is difficult to see how a people who prides itself on its wealth, general intelligence and practical qualities can be longer deterred by skepticism, or motives of convenience and economy, from the adoption of a method of treatment which reduces the mortality of typhoid fever to 3 per cent.

The hypnotics, sulphonal and amylene hydrate, have come into more general use, and prove themselves to be valuable additions to our list of remedies of this class. Unpleasant effects seem rare, while the slow absorption of the one, and the rapid action of the other give each a place.

The treatment of locomotor ataxia by suspension [accidentally hit upon by Motchonkowsky, of Odessa, who was struck by the benefit derived by a tabetic patient, also suffering from spinal curvature, after the suspension required in applying a plaster jacket] has spread with great rapidity, and is being thoroughly tested in this as well as in other countries: It is still too early to determine how useful it will prove to an unfortunate class of patients.

Morton Prince<sup>15</sup> was led by his duties as examiner of applicants for the Boston Fire Department, and by the frequency with which he heard temporary murmurs in vigorous men, to a study of their mode of origin. It has been believed for some years that in debilitated states leakage may take place through the mitral valve, the curtains of which are not tightly closed by reason of the insufficient force of the ventricular contraction. It will be at once appreciated that Prince's cases were the reverse of debilitated; and his ingenious explanation of the murmurs heard in them is that under conditions of great excitement, such as many of the applicants presented, the valve may be forced by ventricular contractions of a power disproportioned to the resistance of the valve. It is not easy to detect a flaw in his argument,

<sup>15</sup> Klinik der Verdauungskrankheiten, Ed. ii, Berlin, 1888

and it seems as if he had made an important addition to our knowledge.

There are many other subjects of which I should like to speak did time permit and were the programme less attractive. Very likely another in my place would have selected quite a different series of topics. The highly-important and interesting subject of cerebral localization, for instance, has not been mentioned. But the work which has been done in that direction the past year has been rather in popularizing previous studies, and in the application of their results to practical surgery, than in new discovery.

Prudden's<sup>16</sup> studies of diphtheria and the constancy with which he finds a streptococcus in diphtheritic lesions deserves more than passing mention. So also, Hare's<sup>17</sup> Fothergillian Prize Essay on "Mediastinal Diseases."

To sum up the results of the year, it may be stated that it has been one of real, though not of brilliant progress. Knowledge has been advanced almost all along the line, more in some parts than in others: bacteriology in its broad sense, including the chemical poisons generated by or accompanying the microbes, as well as the identification and life history of the organisms, offering an enormous field for patient research.

One fact seems to me to stand out in strong relief, namely, that our countrymen are on the high-road leading to the attainment of a reputation for scientific research equal to that which they have long enjoyed in the more immediately practical branches of medicine and surgery.

The future glows with a promise which the achievements of the past assure us will be realized, and it is the part of each one of us, if he cannot discover, at least to do all that in him lies to make the highest and best use of the discoveries of others more gifted than himself.

### TWO CASES OF UPWARD DISLOCATION OF THE STERNAL END OF THE CLAVICLE.

BY S. T. ARMSTRONG, M.D., PH.D.,

ASSISTED ASSISTANT SURGEON U. S. MARINE-HOSPITAL SERVICE.

The comparative rarity of this dislocation, Hamilton<sup>1</sup> mentioning but eleven cases, may justify the publication of the following cases:

*Case 1.*—Jas. Davidson, æt. 41, a native of Scotland, was admitted to the U. S. Marine Hospital, New York, on October 16, 1888, for necrosis of the frontal bone. In examining the patient it was found that he had an old upward dislocation

of the sternal end of the clavicle. The patient stated that in 1881 he fell from a wagon, striking the wheel with his right shoulder in falling. Though severely jarred for a few moments, he felt no severe pain in the shoulder or sternal region, and was not obliged to consult a physician. A machinist by trade; in resuming his occupation the day after his fall, he noticed that in hammering with his right arm he would often miss hitting his chisel fairly. So aggravated did this condition become that he was discharged as incompetent.

Thinking that the accident might have caused his trouble, he consulted a physician some two weeks after the fall, and was informed that the collar bone was dislocated, but that it was too late to do anything to benefit him. As his right arm was apparently as strong as the left he secured employment on a vessel.

The arm has always been servicable. Examination of the chest showed a slight prominence of the sternal end of the right clavicle, that was increased when the arm was extended above the head. If the arm was extended posteriorly there was a slight projection of the bone forward. If the arm was extended anteriorly there was a marked projection of the extremity of the bone, and a knotting of the pectoral muscles beneath it. Moving the arm to the opposite shoulder, the bone glided along the upper margin of the sternum, and could be made to almost touch the opposite clavicle. No movement of the head affected the position of the bone. As the motion in hammering, with the machinist, is largely from the shoulder, there was constant motion of the dislocated extremity; and failure of the pectoralis to have a proper base of support, made the contraction of that muscle in depressing the arm irregular, and hence the failure to strike a true blow with the tool.

The extreme mobility of the sternal extremity leads to the belief that there was originally a laceration of all the surrounding ligaments. There may be partial reformation of the costo-clavicular ligament, but it seems probable that the bone is now held *in situ* by the subclavius muscle.

*Case 2.*—O. Anderson, æt. 39 years, a native of Sweden, was admitted to the hospital April 10, 1889. During a storm at sea, on April 7, a heavy wave struck the vessel he was employed on, and he was thrown against a bulwark; he was unconscious for some time, and on regaining his senses felt a severe pain in his right shoulder and arm, and spit up blood. When admitted to the hospital, a fracture of the right ulna was found. There was emphysema of the right chest, axilla, and shoulder. The right post clavicular fossa was obliterated, and crepitation occurred on pressure here, as well as to the external to the scapula. From this and the pulmonary hæmorrhage a fracture of the ribs posteriorly was diagnosed.

though the site could not be determined as it was covered by the scapula. The sternal extremity of the right clavicle was dislocated upward, and rested on the upper margin of the manubrium sterni; by pressure it could be reduced, but it would gradually slip upward and forward again.

The condition of the patient was such that any attempt at fixation of the dislocated bone was precluded. The patient was kept on his back for two weeks, the fracture of the forearm securing immobilization of the arm. When allowed to sit up the arm was placed in a handkerchief sling, and on May 6, he was discharged recovered.

The sternal end of the clavicle projected, but there seemed to have been a partial reformation of the ligaments, and the range of mobility, of the dislocation was slight. Of course, with constant use, it is possible that the dislocation may be aggravated, but it is improbable that the use of the arm will be interfered with.

These cases simply verify the reported cases: that retention of the dislocation is practically impossible, and that in no case did it impair the usefulness of the arm. Each of the cases were verified by the staff of the hospital.

## MEDICAL PROGRESS.

**BACTERIA IN GREEN SPUTA.**—The occurrence of green sputa is a well-known fact. Formerly all such cases were described by the same name, the green coloring substance was declared to be biliverdin, and in all cases where green sputum was observed, "bilious pneumonia" was diagnosed. At Tranbe's instigation Nothnagel investigated this symptom in the sixties. He arrived at the conclusion that green sputa might originate either from actual admixture of bile coloring substance into the sputa—and this occurs every time when an affection of the respiratory apparatus accompanied by spitting exists with icterus, irrespective of the cause for the latter, consequently not only in pneumonia but also in common bronchitis—or from transformation of a blood coloring matter into a green coloring substance. Nothnagel, who declares that the rust-color of the pneumonic sputa is an early stage of this transformation process, found the last stage, the green color, when the sputum was allowed to remain stagnant for awhile; for instance, in pneumonia terminating in abscess of the lungs, and in subacute catarrhal pneumonia. Later Elliot and Janssen observed a green sputum evidently belonging to this second category in a case of sarcoma of the lungs.

Attention has repeatedly been called to the fact that there are sputa which immediately after expectoration do not show any traces of green color, but which in a few days assume a beautiful green

color. Escherich, Curschmann and Rosenbach have described such sputa. A similar process, in which, however, a yellow color takes the place of the green, was described by Löwer and Traube. The fact that such coloring occurred chiefly in summer, generally wandering in hospital wards from one cuspidor to another, suggested the action of microorganisms as a cause. Especially Rosenbach claimed bacteriological origin for it. Under the microscope he found in his sputa numerous ovoid bodies, small and glittering, which he regarded as bacteria spores. These he thought were the causes, and at the same time the carriers of the coloring substance.

Curschmann, who also investigated the subject, found no trace of bacteria. Nor has thorough examination of this subject, on the basis of our present attainments in bacteriology, ever been made.

Dr. Fricke finally availed himself of an opportunity to do so during an epidemic of green sputa which occurred in the Canton Hospital in Zurich in the spring of 1888. The sputum of a patient with chronic bronchitis had been taken from the medical male ward to the laboratory for the purpose of microscopical investigation. In three days it had assumed a bright green color. Later the sputum of the same patient became green once more, this time in the ward. A few weeks afterwards the patient had to be transferred to the surgical male ward because of hernia, and a few days afterwards the green sputum of a tuberculous patient who had been operated on in the same ward for empyema was shown to Dr. Fricke. It is just possible that there was an etiological connection between the two cases, although the two patients were not in the same room. At about the same time a green sputum from an incipient case of phthisis in the female ward was submitted. The sputa of this last patient for six weeks became green every time that it was left standing for a few days; afterwards the phenomenon suddenly disappeared. Finally one more sample of a sporadic case of green sputum was sent to Dr. Fricke.

At first Dr. Fricke made attempts at vaccination. Into the sputa of various diseases he introduced traces of green sputa, and in two or three days obtained a green color in the former, it making little difference in what disease they originated. Pneumonia sputa turned almost without exception a dark olive-green, sputa of bronchitis assumed a grassy color. Watery or foamy sputa colored badly, and sputa from cavities colored the worst of all. In short, the tendency to change appeared to depend principally upon the physical qualities.

These experiments already proved almost with certainty that microorganisms were the cause of the color. Dr. Fricke now examined all these sputa by means of Koch's plate cultures, and

found in all of them, without exception (besides diverse bacteria which did not produce any coloring matter, and to which he consequently paid no further attention), the same bacillus which upon artificial soil produced a shining green coloring substance, and which, transferred from the pure culture to sputa, produced in them the green color as regularly as the original sputa. Fricke considers, therefore, this bacillus as the only cause of the green coloring substance.

For the non-success in vaccinating certain sputa physical, chemical or bacteriological causes may be held responsible. By the latter Fricke refers to primary occurrence of such bacteria in sputum which do not harmonize with the coloring bacillus, which are antagonistic to the latter. He examined the conduct of the tubercle bacilli in this respect, and found that sputa containing the tubercle bacilli turn green the same as others. He therefore ascribes no clinical significance to the occurrence of the green coloring, as it depends solely upon qualities of the sputa wholly unimportant clinically, and upon the purely accidental entrance of the bacillus. The latter is about the form and size of the typhus bacillus, and having the same brisk motion. It is strictly acrobic. It has no pathogenic qualities.

The coloring substance is not in the bacilli proper, but in the culture media in their vicinity. The production of the coloring matter is not a vital function of the bacillus, Dr. Fricke being able to raise rather a luxuriant growth of them on artificial soil without their producing the coloring substance. It is difficult to obtain the coloring matter in large quantities and still more difficult to produce it in its pure state, as it is insoluble in alcohol, ether, chloroform, etc., but dissolves easily in water and alkali, and is therefore not easy to separate from salts. For this reason an analysis could not be made.

Supplementary to this question Fricke studied all bacilli producing green color which he could obtain. He had cultures sent him from the institutions in Göttingen and Berlin, and thus was able to cultivate beside one another seven different bacilli, six of which produce, when fresh, a shining grassy-green coloring matter: when old, a dirty yellowish-brown color substance which, however, always retains a beautiful green fluorescence, whilst the color substance of the seventh, the *bac. pyocyaneus*  $\beta$  of Ernst, is at first similar to the other, but through shaking with oxygen or through standing for a long time in the air, becomes dark green and finally almost black. The two coloring substances also differ in their relations to acids. The  $\beta$  substance turns red like litmus, the  $\alpha$  matter is completely deprived of color. Alkalies restore to both the original green color.

Three of the seven bacilli dissolve gelatine; they are all known: *Bac. pyocyaneus*  $\alpha$ ,  $\beta$ , and

*B. fluorescens liquefaciens*. Four leave the gelatine unchanged; of these two are movable, two immovable. These differ again in the form of the colonies on the different media. Of the bacilli not dissolving gelatine two are identical with descriptions in the literature: that out of sputa with *Bac. fluorescens putridus auct.* (Flügge), another with *Bac. fluorescens auct.* (Eisenberg); two others have not yet been described. There is also in literature the description of a *Bac. crythrosporus* which likewise produces a green coloring substance, and which distinguishes itself by the formation of large, dirty-red spores. None of the seven kinds above mentioned agreeing with this description, there are consequently eight kinds.

Fricke vaccinated all seven upon sputa, and in all except *Bac. pyocyaneus*  $\beta$  green coloring of the sputa resulted. Consequently one or another of these bacilli might be found in other cases of green sputum.—*Correspondenz-Blatt für Schweizer Aerzte*, No. 9, 1889.

**PATHOGENY OF THE ROUND ULCER OF THE STOMACH.**—There are numerous theories on this subject. According to that most generally accepted there are two factors active in the development of the simple ulcer: a dyscrasic influence, a modification of crasia, such as is found in certain forms of anaemia and in chlorosis, and accidental local influences which produce hæmorrhagic or other ulcerations in the superficial layers of the inner surface of the stomach.

Ingesta may act in both forms, as modifiers of the blood crasia, or as local irritants. It would be interesting to know the relations existing between the different regimens and the occurrence of round ulcer. M. VON SOHLERN has made an investigation in this direction, having sent inquiries to a number of Russian physicians and pathologists to ascertain whether there is any truth in the claim that round ulcer is very rare in a certain part of Russia. The answers received all agree in confirming that statement. As an illustration some statistics furnished by Mr. Winogradoff, prosecutor at the Obuchow Hospital in St. Petersburg, are given here. In about 900 autopsies which are made every year in this hospital, only one or two cases of round ulcer are found. M. Pétersen, prosecutor at the Alexander Hospital, found only three cases of round ulcer in about 6,000 autopsies.

Information gathered by the author from physicians practicing in the Rhön and the Bavarian Alps, two districts in Bavaria, establishes also with surprising certainty the extreme rarity of round ulcer in these two regions. In Russia as well as the two Bavarian districts, the food of the inhabitants is almost exclusively of a vegetable character; meat is consumed only in exceptional cases. The climatic conditions in the two countries differ greatly, the food, too, is quite unlike.

There is only one thing common to the countries where round ulcer is rarely found, and that is the great proportion of potash in the food. To this circumstance the inhabitants of those countries would seem to be indebted for their immunity from round ulcer.—*Gazette Médicale de Paris*, No. 18, 1889.

**INHALATION OF CHLOROFORM IN DISEASES OF THE HEART AND OF THE LUNGS.**—PROF. ROSEN-BACH recommends warmly (*Jour. de méd. de Paris*) inhalations of chloroform in all those cases of lung or heart disease where the other narcotics, as, for instance, morphia, chloral, etc., act too slowly, or where their use is followed by disagreeable secondary symptoms. The method employed by him is as follows. From 5 to 15 gr. of chloroform are put on wadding placed in a funnel, and the patient slowly inhales the vapors from the funnel, which is held at a certain distance from the mouth and nose. As the chloroform is mixed with air there is no danger to be apprehended. The patient at first experiences a disagreeable sensation in the pharynx, but this soon passes off, the patient makes several deep inhalations which produce a feeling of well-being, and sometimes even produce sleep. The author never observed any harmful secondary symptoms ascribable to this treatment.

Chloroform inhalations are indicated in all attacks of dyspnoea of cardiac or pulmonary origin, but especially in emphysema, cardiac asthma, and in heart disease. Good results have also been obtained where they were employed for the attacks so common with phthisical patients. People who previously had been passing their nights absolutely sleepless, slept quite well after resort to the inhalations. Satisfactory results are also obtained in hiccough and in acute cardialgic attacks; in these latter cases, however, morphia is preferable. It deserves to be mentioned that the author succeeded sometimes in breaking up attacks of pulmonary oedema. He also thinks it useful to bathe the tuberculous ulcers of the larynx with a watery solution of chloroform, the improvement ensuing being due, in his opinion, partly to the analgesic and greatly to the antiparasitic action of the chloroform.—*Revue Médicale de l'Est*, No. 9, 1889.

**AORTIC INSUFFICIENCY.**—TIMOFEJEV expresses his opinion on this subject (*Berl. Klin. Wochenschrift*, June 11, 1888) as follows: 1. The diastolic murmur of aortic insufficiency can completely disappear and be replaced by the second normal tone. 2. The intensity of the diastolic murmur depends entirely (a) upon the degree of insufficiency, (b) upon the blood pressure in the aorta. 3. The blood pressure diminishes considerably in the course of valvular affections of the heart. 4. The second tone in the carotid of

dogs in which an aortic insufficiency has been produced, often disappears after a longer or shorter period. 5. The second murmur, which is heard sometimes on a level with the carotid in patients afflicted with aortic insufficiency, is a symptom of purely local origin, and not the continuation of a murmur from the base of the heart. 6. The first murmur which is heard sometimes in aortic insufficiency on a level with the carotid may have a purely local origin.

Rosenbach, however, arrived at contrary conclusions (*Berl. Klin. Woch.*, Sept. 17, 1888). He says: 1. The conditions causing the murmur after artificial destruction of the aortic valve differ essentially in the dog and the rabbit. In the former the murmur is irregular, and may be lacking or disappear in the course of observation, whilst in the latter it is constant and intense. 2. This difference is due to the circumstance that there never occurs precipitation of fibrin upon the injured organs in rabbits, whilst in dogs fibrin-deposits are numerous enough to make up temporarily for the loss of valvular substance. 3. Intra-arterial pressure has no noticeable influence on the intensity of the diastolic murmur, which is chiefly produced by the aspiration of the ventricle dilated by the diastole. 4. The production of the systolic murmur in aortic insufficiency must be ascribed to the backward flow caused, at the beginning of the aorta, by the aspiration of the left ventricle, which current must be overcome by the ventricular contents liberated in the moment of systole.—*Revue des Sciences Médicales*, No. 66, 1889.

**ON DORSAL TABES AND EXOPHTHALMIC GOITRE.**—BARIÉ reports the history of a patient who was affected with various troubles: on the one hand the symptoms of tabes, lightning pains, Romberg's symptom, cessation of the patellar reflex, plantar anaesthesia, incoördination of movements, vertigo, gastric crises; on the other hand the symptoms of Basedow's disease; protrusion of the eye, tachycardia, hypertrophy of the heart, swelling of the thyroid, trembling, polyuria, etc. From this complex of symptoms he concluded that in the course of tabes the classical symptoms of exophthalmic goitre may appear, that these phenomena are the expression not of a disease developing parallel but of a pathological complexus lying in the centers of the medulla; he compares exophthalmic goitre in tabes to the bulbar troubles described by Pierret and Joffroy; he admits that goitre may be a symptom not of the highest stage but of the beginning of tabes which is doubtless related to a simple congestive hyperaemia, and will yield to the use of ergot and faradisation. (*Soc. Méd. des Hôp.*, Dec. 14, 1888). Joffroy reports in brief the cases of seven women afflicted with tabes, all of whom showed tachycardia, whilst six had ocular protrusion, and two

thyroid tumor. He does not share the opinion of Bérié, but thinks that the diseases of Basedow and Duchenne may be seen combined in the same individual; he admits, however, that ataxy may sometimes give way to tachycardia, and perhaps to a slight protrusion of the eye.—*Revue des Sciences Médicales*, No. 66, 1889.

**MUSCULAR ATROPHY IN ATAXIA.**—DÉJÉRINE found in 106 ataxic patients in his practice in Bicêtre, 11 presenting progressive muscular atrophy. He reports 5 clinical cases with autopsy and histological investigation. He concludes that in most cases muscular atrophy in patients with tabes results from neuritis of the peripheral motor-nerves: there exist consequently, besides the cutaneous sensitive neuritis already described by him in 1882, motor-neuritis having much in common with the former; both of them are the more pronounced the farther away from the centres the trunks of the nerves are examined; both of them are also of a peripheral character, for, in the cutaneous neuritis, the spinal ganglions are not affected the same as the interior horns, which are intact in the motor neuritis. The latter should therefore be considered henceforth as belonging to posterior sclerosis, the symptomatology of which they may change in certain cases. (*C. R. Soc. Biol.*, February 25, 1888). Apropos of the investigations of Déjerine regarding the peripheral nature of muscular atrophy in tabes, Joffroy cites several cases of Charcot, Pierret, Londoléo, and of his own practice, in which this atrophy was accompanied either by a lesion in one spot or by a lesion spread out over the motor nerve cells of the anterior horns. Déjerine is of the opinion that in these cases there existed coincidently an acute tephromyelitis, sub-acute or chronic, with ataxy, but not a genuine muscular atrophy in tabes, which can only result from a neuritis of the peripheral motor-nerves.—*Revue des Sciences Médicales*, No. 66, 1889.

**NORMAL AND PATHOLOGICAL CONDITIONS OF GANGLIONS IN THE HUMAN HEART.**—ADOLPH OTT in the "Prager Zeitschrift für Heilkunde," Bd. ix., p. 271, says that ganglion cells are most frequently found in the septum atriorum, that is in its front or rear section, where it is thickest, its thinner middle portion scarcely containing any at all. But also in the circumference of the ventricles, especially in the rear portion, and preferably in that portion of the right ventricle located between the aortic and the pulmonary arteries, the ventricles do not contain any ganglions. The ganglion cells lie principally in the subpericardial connective tissue, but occur also scattered through the muscles. An examination of thirty hearts for pathological changes of the ganglion cells showed that they occur in two types: 1. As a progressive change-growth of connective tissue

between the cells and the nuclei of the Sheath of Schwann with formation of a tissue at first granular subsequently coarsely fibrous; besides in the advanced stages of this process fatty degeneration and compression of the ganglion cells; and secondly, as an acute parenchymatous degeneration of these cells. The former change is found in those cases which lead to stoppage and changes in size in the heart, the latter in complete qualitative alteration of the blood (uræmia, sepsis, etc.) Definite relations between changes of the ganglions and degeneration of the heart muscles cannot be proven. A causal connection between the changes in the heart, microscopically perceivable, and those of the ganglions exist only inasmuch as the stoppage of the blood causing hyperplasia of all tissues in the heart seems to favor also the growth of connective-tissue substances in the ganglions and its consequences. For clinical purposes the result of the investigation do not furnish any material which would allow of drawing a conclusion from the heart action as observed during life upon the pathological conditions of the ganglions of the heart, or which permit an influence upon the action of the heart, *i. e.*, its frequency or rhythm on the part of the changed ganglions to be recognized.—*Centralblatt für Klinische Medizin*, No. 15, 1889.

**POISONING BY PTOMAINES.**—M. MERVILLE reports a case where a family was poisoned by eating bouillon which was only one day old, but had been kept in a bedroom and had not been boiled over. The symptoms of the patients were very similar to those of cholera: incessant vomiting, abundant rice-like stools, cramps in the limbs, cyanosis, etc. The condition of the patients was very serious, but all recovered. This was evidently a case of poisoning by ptomaines which had formed in bouillon made of sound meat, large quantities of the soup having been eaten on the first day without causing any trouble whatever.—*Gazette Médicale*, No. 32, 1889.

**ON TUBERCULOSIS OF THE LUNGS IN SUGAR-DIABETES.**—A. BAGOU shows that phthisis in diabetic patients is always of a tubercular character, whatever its clinical form may be. Whether acute or chronic, or pneumonic or ulcerative; it always has the bacillus for an anatomical substratum which invades the organism all the more easily as it finds it debilitated with the impregnation with sugar. The immediate cause for tuberculosis in diabetes is the diminution of resistance of the organism. Clinically it is specially characteristic of this kind of phthisis to appear insidiously to cause but little hæmoptysis, little febrile reaction, hardly any perspiration. But from a prognostic standpoint it is of the most malignant type as it never improves.—*Revue des Sciences Médicales*, No. 66, 1889.

PER ANNUM, IN ADVANCE.....\$5.00  
SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
NO. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JULY 6, 1889.

FORTIETH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

The first General Session of the Association assembled in the Music Hall at the hour named upon the programme. The meeting was called to order by the Chairman of the Committee of Arrangements, Dr. H. R. Storer, of Newport, who presented the President of the Association, Dr. W. W. Dawson. After prayer by the venerable Dr. Thayer, the senior clergyman of Newport, letters of regret were read from the following: Vice-President L. P. Morton; Hon. J. W. Noble, Secretary of the Interior; Hon. B. F. Tracy, Secretary of War; Hon. John Wanamaker, Postmaster-General; Hon. W. Windom, Secretary of the Treasury; Drs. Stillé, E. H. Gregory, Ex-Presidents of the Association; Dr. H. I. Bowditch, of Boston; Dr. W. B. Geikie, Dean of Trinity Medical College, Toronto; Dr. Montizambert, Medical Superintendent at Grosse Isle, Quebec; Sir James Grant, M.D., Ottawa, Can.; Sir Charles Tupper, M.D., Minister of Marine and Fisheries, Can.; Dr. P. H. Bryce, Provincial Board of Health, Ontario; Professor James C. Cameron, Montreal; and others.

Various letters of invitation were then read, one of the most important being that from the Faculty of Harvard University inviting the members of the Association to visit the College on their return home.

The Hon. H. W. Ladd, Governor of Rhode Island, addressed the Association in terms of welcome. He said that Rhode Island was noted for

its hospitality, and that the Association would find that its reputation would be maintained in that instance.

The Hon. Jas. H. Eldridge, M.D., of East Greenwich, welcomed the Association in the name of the profession of the State of Rhode Island (See p. 14).

The Presidential Address, a full report of which may be found in the fore part of this issue of THE JOURNAL, was read by Dr. J. A. Larabee, of Louisville. Dr. Dawson, the President, though present, found himself unequal to the task of delivering it on account of ill-health.

The proceedings of the second day were opened with prayer by the Rt. Rev. T. M. Clark, Bishop of Rhode Island. After the reading of announcements and the report of elections to the Nominating Committee, an Address on Medicine was delivered by Dr. Wm. Pepper, Provost of the University of Pennsylvania.

Dr. Pepper's address consisted of an interesting account of the life and labors of Dr. Benj. Rush, together with an eulogy of his character. The address was a most eloquent tribute to the memory of the first of our great American physicians. Dr. Pepper reviewed his life in considerable detail, but dwelt more upon his personal characteristics and the part he played in the contemporaneous history of his times, pointing out the manifold character of his work as a statesman, a literateur, a reformer and, most of all, a physician. As a medical officer of the Army, as the projector of the Philadelphia Dispensary, as a political, social, and medical reformer, his work was of the highest character. His essay on "The Physical Influence on the Moral Faculty" occupies a classical position in the literature of medicine. His efforts in opposition to capital punishment, slavery, intemperance, and the use of tobacco were of the most earnest and effective nature. He drew much of his inspiration from his friend, Franklin, as well as from his great teacher, Sydenham. He was not only a master of literary style but a most eloquent and effective speaker. He was an active and progressive educator. Through all his writings there runs a vein of piety free from sectarianism. After 1789 the greater part of his work was medical, while the most interesting part of his life was that subsequent to his election to the University of Pennsylvania. From this date,

1789, to the date of his death, 1813, the history of his life is the history of American medicine—the "Era of Rush." As a medical teacher he was unrivaled for simplicity. His history of the epidemic of 1793 is one of the very best ever published. Dr. Pepper fears that in these days refinement in diagnosis and the study of disease often leads to the loss of valuable time, and that Sydenham's belief that the prompt treatment of disease in its incipency is one of the most important elements in our success as physicians, as it was in the case of his pupil Rush. Our own resources are much greater now than were theirs in the last century. We are often in danger from too great refinement. They had few and trusted remedies. We have many remedies for every symptom and do not thoroughly learn the use of any of them.

Dr. Gihon, U. S. N., Chairman of the Rush Monument Committee, then presented his annual report. He regretted that the Committee could not report progress, and feared that the members would not live to see the fruition of hopes indulged five years ago when the Committee was appointed. The treasurer had only received \$1,000. After a most energetic appeal to the whole profession for aid in this important movement, he announced that the dollar limit had been abandoned and that sums of any amount would be received. In the midst of much enthusiasm the sum of \$264.50 was soon added to the fund.

The debate on adoption of amendments to Constitution then followed.

The amendment to strike out the last clause of Sec. VII, relating to individually affixing names to the Constitution and regulations of this Association, was adopted.

The amendment proposed by Dr. Moyer, referring to changes in the Constitution of the Sections, was indefinitely postponed.

After a lively debate the resolution affecting the personal duties of the General Committee was lost.

The proceedings of the third day were opened with prayer by the Rev. James Coyle, (R. C.) of Newport.

The Address on General Surgery was then given by Dr. Phineas S. Conner, of Cincinnati, and will be found reported in full in this issue of THE JOURNAL.

Dr. R. J. Dunglison, of Philadelphia, presented his annual report as Treasurer which showed the Association to be in satisfactory financial condition.

The Nominating Committee then made their report, after which it was decided to hold the next meeting at Nashville, Tenn., on the third Tuesday in May, 1890.

The following officers were elected: President, E. M. Moore, of New York; First Vice-President, J. W. Jackson, of Missouri; Second Vice-President, W. W. Kimball, of Minnesota; Third Vice-President, J. H. Warren, of Massachusetts; Fourth Vice-President, T. B. Evans, of Maryland; Treasurer, R. J. Dunglison, of Pennsylvania; Permanent Secretary, W. B. Atkinson, of Pennsylvania; Librarian, C. H. A. Kleinschmidt, D. C. To deliver Address on General Medicine: Dr. N. S. Davis, of Illinois; General Surgery, Hunter McGuire, of Virginia; State Medicine, Alfred L. Carroll, of New York.

The Hon. Geo. Bancroft, and Sir James Grant, of Ottawa, were then presented to the Association, the latter making a few remarks in which he dwelt upon the advances made during the past half century in the treatment of insanity, and referred to the advances made in the surgery of the thorax. The subjects of medical education and examination were touched upon, and he recommended that the best way to weed out irregular practitioners is to require "a rigid preliminary training."

The fourth day's proceedings were opened with prayer by the Rev. D. A. Jordan, (M.E.), after which Dr. W. H. Welch, of Baltimore, delivered the Address on State Medicine, a full report of which will be published in a future issue of THE JOURNAL.

Dr. J. M. Toner, Chairman of the Committee on Necrology, presented his annual report.

The full Official Report of the Proceedings of the Fortieth Annual Meeting of the Association will be published in THE JOURNAL as soon as received from the Permanent Secretary, Dr. W. K. Atkinson, of Philadelphia.

THE WEEKLY MEDICAL REVIEW, of St. Louis, will be enlarged to the size of the *New York Medical Journal*.

## EDITORIAL NOTES.

## HOME.

UNIVERSITY OF PENNSYLVANIA.—The Associate professorships of Obstetrics in the Medical Department of the University will be consolidated and Dr. Barton C. Hirst elected as Professor of Obstetrics. Dr. William Goodell will continue his duties as Professor of Gynecology.

THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA will hold its twenty-second annual meeting at White Sulphur Springs from July 17-19, 1889. Full particulars as to railroad arrangements, etc., may be learned on application to the Secretary, Dr. J. L. Fullerton, Charleston, W. Va.

THE CHICAGO POLICLINIC is now an assured success. The enterprising Faculty have commenced the erection of a handsome four-story structure on Chicago avenue, west of Wells street. The exterior will be constructed of brick and stone, and the interior finished in hardwood and heated by steam. It will cost \$25,000 and will be completed in about four weeks.

THE OHIO STATE MEDICAL SOCIETY.—At the forty-fourth annual session of this Society, recently held in Youngstown, O., the following gentlemen were elected officers: President, Dr. John McCurdy, of Youngstown; Vice-Presidents, Drs. J. W. Conklin, of Dayton; A. W. Ridenour, of Massillon; C. W. Tanagerman, of Cincinnati; J. E. Woodbridge, of Youngstown; Secretary, Dr. G. A. Collamore, of Toledo; Assistant Secretary, Dr. E. C. Brush, of Zanesville; Treasurer and Librarian, Dr. T. W. Jones, of Columbus. The next meeting will be held at Columbus, the first Wednesday in June, 1890.

## FOREIGN.

DR. QUAIN, F.R.S., has received the appointment of physician-extraordinary to Queen Victoria.

PROF. LÖWENTHAL has received a special mission from the French Government to proceed to Tonquin to study the effects of salol on cholera patients.

THE TENTH INTERNATIONAL MEDICAL CONGRESS.—Professors Virchow, von Bergmann, and Waldeyer have charge of the preliminary work for the next Congress, and are actively engaged

in maturing plans to make it a great success. There will be a conference of delegates from all the medical bodies in Germany at Heidelberg in September. It is likely the Congress will commence its proceedings on August 6, 1890.

IN FRANCE death by electricity has fascinated the French. The Parisians have petitioned the Municipal Council of Paris to substitute the electric current for the guillotine as a more merciful method of capital punishment. The meteorological observatory on the Eiffel Tower is now at work. The direction and force of the wind, the moisture and dryness of the atmosphere, the variations of temperature, cloud observations and weather forecasts will be minutely recorded, and the reports placarded in the Exhibition buildings proper.

IN ITALY Prof. Taurini recently successfully performed total extirpation of the clavicle for myxo-sarcoma. Several prominent members of the medical profession have recently died: Enrico Albanese, professor of clinical surgery in the University of Palermo, died of Addison's disease on April 8; Dr. Davis Maragliano, professor of psychiatrics in the University of Genoa; Dr. Luigi Barzanò, a pioneer of electro-therapeutics in Italy; Dr. E. Bonamici, lecturer on materia medica and toxicology at Florence; and Dr. A. De Marchi Gherini, the leading surgeon in Milan.

IN EGYPT the epidemic of typhus fever has almost entirely yielded to energetic measures. Small-pox is prevalent. Dr. Hassan Pacha Mahmoud claims to be the discoverer of an affection which he names *bouton d'Egypte*. He states that the *bouton* is peculiar to Egypt, is non-contagious, contains no trace of microbe, differs from an ordinary furuncle, is superficial, leaves no traces on the skin, may last from twelve to fourteen years, and owes its origin to the action of the air and sun. Rabies is present in Egypt. In Cairo and Helouan 13,326 dogs have been poisoned within fifteen months.

IN INDIA the Government is taking stringent precautions against the spread of leprosy, and it is proposed to empower the district magistrates to arrest any leper found wandering about without means of subsistence. These may be detained in a retreat for life. Every retreat is to provide for the complete separation of the sexes. Great dis-

tress prevails in some districts. In Ganjam, where the situation is worst, no drinking water remains in the tanks, and cholera is epidemic throughout the district.

## SOCIETY PROCEEDINGS.

### American Medical Editors' Association.

*Annual Meeting, held at Newport, R. I.,  
June 23, 1880.*

W. C. WILE, M.D., PRESIDENT, IN THE  
CHAIR.

The American Medical Editors' Association met at 8:30 P.M. The meeting was called to order by the President, Dr. Wm. C. Wile.

DR. WM. BRODIE, of Detroit, was invited to occupy the Chair during the reading of the *Presidential Address*.

(See page 10.)

In the discussion which ensued DR. BRODIE, of Detroit, said he thought there were too many journals and too few good journalists. There is too much work done with the scissors. Many good papers are lost by being published in short-lived journals. He believed that THE JOURNAL of the Association should be conducted on a thoroughly impersonal plan, in which the identity of the editor is wholly lost to view. THE JOURNAL had done much good work in killing off other journals of little value.

DR. DULLES, of Philadelphia, said he believed it the duty of medical editors to foster good journals and kill the bad ones. He emphasized the necessity of maintaining a high ethical and literary standard and of promoting brotherhood in the profession.

DR. LEARTUS CONNOR, of Detroit, believed that idealism in medical journalism does not pay. Some of the most wretched journals pay the best. He was reminded of the tobacco manufacturer who said that if one would be rich he should pander to the *vices* of the people.

DR. I. N. LOVE, of St. Louis, did not take the same pessimistic views that some of the other speakers had expressed. He believed that Darwin's law holds good in journalism as in animal life.

DR. N. S. DAVIS, of Chicago, in his most vigorous manner rebuked the patronizing of foreign schools to the neglect of our own, and asserted that one-fourth of the money expended by our students in foreign countries would serve to perfect our own valuable institutions.

DR. T. D. CROTHERS, of Hartford, read a paper on

### THE INFLUENCE OF MEDICAL JOURNALISM ON THE MARCH OF SCIENCE.

He believed that the influence of the medical journal could scarcely be overestimated. Medical journals may be divided into three classes: the general, the special, and the encyclopædic, each of which has its own value. Quarterlies are doomed, while the others are constantly increasing their usefulness. At present the weekly journal is the type, but in the near future we may look for the medical daily.

DR. PANCOAST, of Philadelphia, said he deplored the failure to report the daily work of the clinics. The weekly journal should be a mirror of the medical and surgical work done in the clinics of each community. We look to the journal for the knowledge we need in our daily work. He does not share in the pessimistic views expressed by some of the journalists present but on the other hand had much reason to praise our own journals and criticise those of foreign lands.

DR. CONNOR dwelt on the necessity of putting well-digested materials before the readers, but warned his hearers against the danger of emasculating good articles by cutting them down.

DR. WAUGH, of Philadelphia, found little in what had been said during the discussion with which he could agree. What is ideal reading for one cannot be ideal for all. As for special journals, there are not specialists enough to support them, whereas culled special matter may well enliven the columns of a general journal.

DR. STORER, of Newport, found much satisfaction in the thought that the plan which he indorsed eighteen years ago, of founding a weekly journal as the organ of the American Medical Association had met with such great success.

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*The Academy of Medicine: Dr. P. A. Morrow relates some Personal Observations of Leprosy—Discussion on the Danger of the spread of Leprosy.*

At the last scientific meeting of the Academy of Medicine for the present season Dr. P. A. Morrow gave some interesting personal observations of leprosy, recently made in Mexico and the Sandwich Islands, with magic lantern illustrations of typical cases. He said that leprosy was too often looked upon as possessing only a historic interest, like the plague and other diseases of former times. It would not do, however, to so regard it. Unfortunately, it was a living reality, and a map representing the geographical distribution of the disease would show that it extended over fully

one-third the surface of the globe. This general distribution, he believed, had a very important bearing upon its etiology. It was impossible to give the exact number of lepers at present in the world, but in India alone there were certainly not less than 150,000.

The importation of leprosy from a country where the disease was endemic to one where it had been previously unknown, he said, could always be traced to the agency of personal contact. In our own country the cases of the disease could be traced to three or four distinct sources. In Louisiana it had been introduced by the Acadians when they settled there in 1758. In Iowa, Wisconsin, Minnesota and Illinois it had been introduced by Scandinavian immigrants; and in California and Oregon by the Chinese. He had recently become aware of the hitherto unknown existence of the disease in Great Salt Lake City, where it had been brought by natives of the Sandwich Islands.

Dr. Morrow's personal observations began in New Orleans, where Dr. Blanc reported the existence of forty-two cases last year; these being entirely independent of the lepers of the Teche River district of Louisiana. In Mexico leprosy had existed ever since the time of Cortez, who established a lazaretto which continued in use until about thirty years ago. Since that time lepers had been cared for in the general hospitals, and numbers of these people might be met with in the streets of Mexico at any time. At San Francisco he saw quite a number of cases; six of them being in the pest-house there. The Sandwich Islands, he thought, offered probably the best field in the world for the study of leprosy, on account of the comparatively recent origin and great prevalence of the disease there. Segregation had been secured by the establishment of an isolated leper settlement, and there were now more than 11,000 cases at it.

It was only within the last twenty-five years, he went on to say, that the true character of leprosy has been ascertained. We now know that it is a parasitic disease; and the bacillus lepra discovered by Hausen presents certain analogies to the tubercle bacillus. This is particularly true as regards its remarkable vital tenacity. Like all specific microbes, it has an elective affinity for certain fluids and tissues of the body. As regards the origin of leprosy, he said it could be stated positively that the disease never originated spontaneously. It does not attach to the soil, water or food, but is always communicated from an individual, and can always be traced to personal contact. Its period of incubation is a long one. This is variously stated at from three to five years, but in certain instances seems to be from ten to fifteen years. It is a very difficult matter to arrive at the exact period of incubation, because there is no initial lesion, and the prodromal symptoms are

very indefinite. The progress of the disease is slow, but it almost invariably terminates fatally.

There are several moot points in regard to the disease, and the first of these is as to its contagiousness. This has never been at all questioned until comparatively recent times; but about thirty years ago it began to be doubted. It is worthy of note, Dr. Morrow thought, that the leading dermatologists of New York have never accepted the heresy of the non-contagiousness of leprosy. The history of the disease in the Sandwich Islands afforded the most conclusive proof of its contagiousness. In no other way could its rapid spread throughout the race be accounted for; at the present day from 5 to 10 per cent. of the native population being lepers. In investigating the disease one can get a history of personal exposure in almost every instance. At the leper settlement many of the patients are incapacitated from taking care of themselves, and are obliged to have relatives or friends to look after them, who are presumably free from the disease when they go there. It has been observed that a very large number of these attendants after a time contract the disease; and it is also a well-known fact that a considerable number of foreigners living in the Sandwich Islands have become victims to leprosy.

As to the modes of infection, our knowledge is not positive; but in a large proportion of cases this is probably by sexual intercourse. It seems probable that the disease may be contracted through abrasions of the mucous membrane or skin, and also by means of animal parasites or the bites of mosquitoes and other insects. Vaccination has undoubtedly been one of the causes of the spread of leprosy, humanized virus being used, and no distinction being made between healthy and unhealthy subjects in procuring the virus. Inoculation of leprosy has been successfully carried out in one instance, the subject being a condemned criminal. Dr. Morrow said he had seen one case in which the patient claimed to have contracted the disease from the bite of a leper, and another in which the patient stated that it came from the prick of a pin with which a leprous boy had amused himself by sticking it into his body.

Another moot point is that of heredity. Formerly this was regarded as positively established, and in all ages it has been looked upon as the principal cause of the disease. In his personal observations, however, he said he found no proof whatever to support the view of heredity. A predisposition to leprosy might be transmitted, as in the case of tuberculosis; but he did not believe that the actual germs were ever so transmitted. There is not a single case of congenital leprosy on record. In instances of suspected heredity the child never shows evidences of the disease under the age of 3 years, and usually not until puberty. In general, the disease develops only in those

from 30 to 50 years old. Leprosy, then, is either analogous to late syphilis or else it is not transmitted at all to offspring. Observation shows that the children of lepers do not become infected unless they are kept in close contact with their parents. Very few living children are born in the leper settlement. For seven years there were only two; and later, of twenty-six infants that lived, nine presented evidences of the disease between the ages of 3 and 14, while the remainder escaped infection entirely. It is altogether probable, therefore, that in all cases of suspected heredity the disease is really due to post-natal contagion.

Among the photographic slides thrown upon the screen was one of the late heroic Father Damien, taken only six weeks before his death, and also one of the convict upon whom inoculation was successfully practiced, the only case on record. This man, who had been condemned to death, was given his choice between execution and imprisonment for life with inoculation with leprosy; and the inoculation was made by Dr. Arning in September, 1884. Bacilli were found in numbers about the inoculated spot until March, 1885, after which they gradually diminished in number. For several years the result was regarded as negative, but more recently evidences of infection have developed, and at the present day there can be no question of his having well-marked leprosy.

A discussion then followed in regard to the danger of the spread of leprosy in this country. It was opened by Dr. Morrow, who expressed the opinion that such a danger actually exists, and said that the disease in its present state here might be compared to a conflagration, which could easily be extinguished at first, but which, left to itself until it had gained a certain headway, could not be subdued until all the material it had to feed upon had become exhausted. In the Sandwich Islands in 1848 there were but few cases of leprosy, and for twenty years the Government paid no attention to the disease. By that time there were about 250 cases, and the authorities, becoming alarmed, took stringent measures for its suppression. A system of segregation was adopted, but, unfortunately, the danger was appreciated too late. He did not believe that such a fate as that of the Sandwich Islands was in store for the United States; but, at the same time, he thought there was a sufficiency of leprosy seed here to stock this or any other country. The only question was, whether the soil was favorable for the development of the disease. Any one who believed in the contagiousness of leprosy, must assume either that a great danger menaces us, or else that the conditions of our civilization are not favorable for the spread of leprosy.

He went on to say that, in his opinion, the danger was not such as seriously menaced the public health, as the disease would spread very slowly, if at all. At the same time it should be

borne in mind that leprosy is a disease in which the resources of medical science are futile, and measures should therefore be taken to stamp it out. It is probable that there are more cases in this country now than ever before. The report of forty-two cases in New Orleans last year was a surprise to every one, and the propriety of legislative enactment for the suppression of the disease is unquestionable.

Dr. C. W. Allen said that his convictions on this subject were very decided. Two years ago, in a paper read before the Medical Society of the County of New York, he had contended that lepers should not be admitted to this country, and that those already here should be segregated. Two years ago he had placed the number of cases in the United States. This number, he had reason to believe, was too small at that time, and he thought there could be no doubt that there had been a considerable increase since then. When we considered the number of cases already existing, and the increased likelihood of the spread of the disease from the increasing facilities of modern travel, etc., this question became one that we could no longer shut our eyes to. Of the forty-two cases reported in New Orleans, where no leprosy was supposed to exist, twenty-nine were natives of Louisiana, and twenty-two of the city of New Orleans. One of these had been a nurse in a hospital where a leper was under treatment. The evidences of the contagiousness of the disease were positive, and as long as a single leper existed anywhere he would constitute a source of danger to those about him.

Dr. L. D. Bulkley said he regarded this subject as one of the most important ever brought before the Academy. No one could fail to see, he thought, that whenever leprosy has been allowed free scope it has spread; while, on the other hand, whenever proper measures have been taken in time against its spread, it has been exterminated. There seemed to him a propriety in having the matter agitated, and he thought the least the health authorities could do would be to ascertain the number and condition of the lepers now in this country. For the last twenty years he had seen two or three cases every year in New York. One case he had met with in a patient who had never traveled many miles from Poughkeepsie, where he lived, and another in one who had never been far from New York. Precisely how they contracted the disease he did not know, but there could be no question that they had derived it from antecedent cases. Leprosy always came from leprosy. He differed from Dr. Morrow, however, in the opinion that the bacillus lepræ does not exist in the soil, water, etc., and believed that it may be left there like other germs. In concluding he said he thought it would be well to appoint a committee to report on the question under discussion at some future time.

Dr. George H. Fox said that the exciting of alarm seemed to him objectionable on account of the false assumption that there has been a spread of leprosy in this country. The cases met with here were nearly all imported, and in spite of the fact that there was no law prohibiting the entrance of lepers, and that no segregation was practiced, he believed that the number at present was smaller than at former periods. Some of the cases formerly here had died, and others had left the country. He also knew of one case at least in which the patient considered himself cured; no signs of the disease having appeared for six years. He admitted that there was a slight danger from the lepers still remaining; but so there was, he said, from hydrophobia. As a rule, the whites of the Sandwich Islands were free from leprosy; and he had yet to learn of an instance of the spread of the disease in a white civilized country. Its prevalence among the Hawaiians, he believed, was in great part attributable to their uncleanly habits and mode of living. The danger was of course greater, the greater the number of lepers; but it was very rare for nurses, sisters of charity and others in constant attendance upon leprous patients to contract the disease. All lepers, he thought, should be prevented from landing here, as the paupers were, not so much from the likelihood of their spreading the disease as because, like paupers, they would be a burden on the community. The popular dread of this disease was unfounded and absurd, and even physicians shuddered at the name of leprosy while they looked with complacency upon syphilis and tuberculosis.

Dr. H. G. Piffard said that ten years ago he had read a paper before the Academy in which he discussed the question now raised, and since then his views had not altered. The points for which he contended at that time were, first, that leprosy is contagious; second, that lepers should be segregated; third, that it is the function of the National Government to attend to this. At this meeting a committee was appointed from the Academy to investigate the subject of leprosy in this country, and the committee performed the work required of it so far as it was possible to do so. It did not succeed, however, in tracing out more than forty or fifty cases in the United States; many cases, no doubt, escaping observation.

It was his opinion that, at the present time, there were at least five times as many lepers in the country as there were ten years ago. That segregation was necessary was shown by the fact that wherever this has not been carried out the disease has increased, not in arithmetical, but in geometrical progression. To the question, whose charge is it to attend to this segregation? he would answer, the National Government's. The Government should, in the first place, prevent the entrance of all lepers into the country; and secondly, induce, as far as possible, all lepers now

here to go to properly appointed lazarettos. It should be the duty of each State to place its own lepers in these lazarettos. Whether the present discussion could have any practical effect he thought was very doubtful. Not until the necessity of taking active measures to prevent the spread of leprosy forced itself upon public attention would anything be done; but that time, he believed, would surely come sooner or later.

Dr. F. R. Sturgis said he believed that Dr. Morrow was right in stating that there was no immediate danger to the public health from this source, but that it was undoubtedly the duty of the medical profession to call attention to the matter. Up to the present time the evidence of direct inoculation with leprosy had been lacking; but the case of the criminal referred to really seemed to show the possibility of inoculation, and further confirm the contagiousness of the disease. It was probable that leprosy followed a course similar to that of syphilis; being more contagious than in its later stages. As to the bacillus mentioned, he did not think it has as yet been proved to be the cause of the disease, any more than was the case in regard to the so-called bacillus of syphilis. Dr. Fox depended on negative evidence for the position which he assumed; but one positive case was of greater value than all such negative evidence. In our crowded and filthy lodging-houses he believed there existed all the conditions favorable to the development of leprosy if the contagium was once introduced. As to the comparative risk from leprosy and syphilis, he said he would rather run his chances with the latter, as there was, so far as he knew, no cure for leprosy. Syphilis might be ten times more contagious than leprosy, but leprosy was ten times as dangerous.

In closing the discussion Dr. Morrow said there seemed to him but little doubt that the leprosy in the case of the criminal mentioned was positively caused by the inoculation. This was made in 1884, and the four years that elapsed before leprosy made its appearance corresponded entirely with the ordinary incubation period of the disease. It was an important fact, he thought, that the spread of leprosy in the Sandwich Islands had occurred under conditions of high civilization; the state of the population being greatly superior to what it was fifty years before. Dr. Fox labored under a misapprehension in regard to the people there, who were in reality infinitely better off than the majority of the poorer classes in this country. They were accustomed to bathe four or five times a day, and were otherwise cleanly in their habits. Yet, notwithstanding their improved condition, the scourge of leprosy had attained the most fearful proportions among them.

In regard to the contagiousness of the disease, there was one point which offered a possible explanation of the difference of opinion which had

existed concerning it. He thought it extremely doubtful whether the anæsthetic type of leprosy was capable of transmitting the disease. It was this form, rather than the tubercular, which predominated in India and Mexico to-day, and in this the bacilli were not found in the external lesions. To his mind the evidences of contagiousness abounded and superabounded. He did not wish to be considered an alarmist, but in regard to this disease he believed that a wholesome dread was better than a false security. By the adoption of active measures he thought it could be stamped out absolutely. At the conclusion of his remarks Dr. Morrow exhibited under the microscope specimens of the bacillus lepræ which had retained their vitality for a very long period. P. B. P.

## NECROLOGY.

### Dr. F. H. Rehwinkle.

We regret to announce the death of Dr. F. H. Rehwinkle, of Chillicothe, O., who succumbed on the 7th ult. from the effects of a stroke of paralysis. The stroke came to the doctor as it always comes, suddenly, and without a moment's warning—if one overlook the haggard and broken-down condition which had been apparent in Dr. Rehwinkle for the past year. He had gone across the street after supper, and consenting to take a drive with Dr. Searce, had gotten into the buggy and sat there talking and laughing with the doctor's daughter, Miss Lizzie, awaiting the doctor's readiness. When Dr. Searce got into the buggy and took the lines, and Dr. Rehwinkle bade Miss Lizzie good evening, there was no indication whatever of the terrible affliction that was about to befall him; but the horse had not taken twenty steps when, in the reply to a question that Dr. Searce put to his companion, he observed that something was wrong. Observing him more closely when they reached a point near the postoffice, he remarked, "Doctor, you are sick!" and immediately turning around drove back to Dr. Rehwinkel's house, less than a hundred yards distant, but with the wreck of the alert, intelligent and sentient human being who had left there but a moment before. With assistance he was carried into the house, and to his room, where an examination of the patient showed that there was complete paralysis of the left side. He afterwards sank into a half-comatose condition, though able to recognize his relatives and friends, and in that condition had remained up to the time of his death.

The most intimate friends of Dr. Rehwinkle have known for some time past that he feared what has now happened. It was only a short time ago that he remarked in casual conversation with

a party of friends, "I believe that I will die of paralysis; and I fear at times that the stroke has been hanging over me for months, and that it may fall at any moment." All his friends had noticed how terribly he had aged within the past year; how worn and haggard he had looked; and it has been a source of frequent, sympathetic and regretful comment among them. He had complained for some time of an unpleasant sensation in the neighborhood of the heart, and this, and the fancied symptoms of paralysis have been such as to prevent him from venturing from home any distance.

Dr. Rehwinkle has been regarded as a dental surgeon of extraordinary science and skill; few or no surgeons in the state ranking higher than he in his chosen profession. To him was accorded the compliment of appointment as one of the three American Secretaries to the International Congress of Dental Surgeons, which assembled at Washington D. C., in 1887; and upon him fell a large proportion of the work of preparation for that meeting.

Dr. Rehwinkle was a member of the American Medical Association, and Chairman of the Section on Dental and Oral Surgery.

## MISCELLANY.

THE 75,000 EDITION.—The *Chicago Medical Journal and Examiner* says:

The business manager of THE JOURNAL of the Association has issued an extra edition of seventy-five thousand copies of THE JOURNAL, which contains a carefully prepared report of the requirements of the various medical colleges of the United States and Canada, compiled by Dr. W. G. Eggleston, formerly assistant editor of THE JOURNAL.

The additional work involved in issuing this large edition has been considerable, and it is to be hoped that it will be the means of advancing the interests of the Association and of its official organ, and thus reward the business manager for his faithful efforts to serve both.

MEDICAL SOCIETY NOTES.—The semi-annual meeting of the Medical Society of Fulton County, N.Y., was held at Gloversville on the 18th ult. "Modern Treatment of Wounds" was the subject of a paper read by Dr. F. Drury, of Broadalbin. Dr. W. C. Wood read a paper on "Lazy Therapeutics." Miss M. Helen Cullings was admitted to membership.

At the annual meeting of the Rochester Pathological Society, held recently, the following were elected officers for the ensuing year: President, Dr. Benjamin Wilson; Vice-President, Dr. E. T. Dow; Secretary, Dr. Ogden Backus. Dr. E. W. Mulligan, the retiring President, read a paper on "Microscopy in Medicine."

HEALTH IN MICHIGAN, MAY, 1889.—For the month of May, 1889, compared with the preceding month, the reports indicate that diarrhoea and inflammation of kidney increased, and that influenza, remittent fever, pneumonia, erysipelas and pleuritis decreased in prevalence.

Compared with the preceding month, the temperature in the month of May, 1889, was higher, the absolute humidity was more, the relative humidity and the day and the night ozone were less.

Compared with the average for the month of May in the three years, 1886-88, tonsillitis increased, and measles, consumption of lungs, erysipelas and remittent fever were less prevalent in May, 1889.

For the month of May, 1889, compared with the average of corresponding months in the three years 1886-'88, the temperature was slightly lower, the absolute and the relative humidity were slightly less, and the day and the night ozone were about the same.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of May, 1889, at 22 places, scarlet fever at 48 places, typhoid fever at 10 places, measles at 23 places, and small-pox at 2 places.

Reports from all sources show diphtheria reported at 1 place less, scarlet fever at 5 places more, typhoid fever at 5 places more, measles at 9 places more, and small-pox at 1 place more in the month of May, 1889, than in the preceding month.

**THIRTY-ONE YEARS A UNIVERSITY PROFESSOR.**—The resignation of Dr. T. G. Richardson from the faculty of the Tulane University, brought forth the following expression from his fellow-members of the faculty:

MEDICAL DEPARTMENT, )  
Tulane University of Louisiana, )  
New Orleans, May 20, 1889. )

WHEREAS, Prof. T. G. Richardson, who has served the medical department thirty-one years—fourteen years as Professor of Anatomy and seventeen as Professor of Surgery, including twenty years as Dean—has urged the acceptance of his own resignation because of ill-health; therefore be it

*Resolved*, That Prof. Richardson's resignation is accepted with the utmost regret, this faculty being thereby deprived of its most valued member and its wisest counselor.

*Resolved*, That the members of this faculty can never forget that his inflexible devotion to truth, honor and duty furnished for their guidance the highest and noblest standard of true manhood; that his ability and experience as a teacher placed him in the foremost rank of medical instructors; that his wisdom as Dean successfully guided the destiny of the medical department through many years of its severest trial; and that to him, more than to any other, is due its present prosperity.

*Resolved*, That while deeply deploring the necessity that withdraws from active service our senior professor, yet our hearts are revived by the hope that time and rest will restore him to health and give to him many happy and useful years wherewith to bless his family and his friends and to benefit all of his fellow-citizens.

*Resolved*, That Dr. T. G. Richardson is hereby chosen Emeritus Professor of Surgery.

Signed by Stanford E. Chaillé, M.D., Dean; Ernest S. Lewis, M.D., Jno. B. Elliott, M.D., committee in behalf of a unanimous faculty.

**SUMMER DIARRHŒA.**—*The Medical Record* says: The period has come when the well-to-do minority of physicians leaves the city, while the hard-working majority stays in town and writes articles on summer diarrhœa and related topics. Fortunately, something new is furnished us every year on these matters. We have passed from the stage of heat and sour milk as causative factors of summer diarrhœa; we are even leaving the microbe a little behind, and are dallying now with the ptomaines. The latest theory is one set forth by Dr. Ballard, in a report to the Local Government Board of England on the causation of the annual mortality from diarrhœa (*Lancet*). Dr. Ballard states his views as follows: "That the essential cause of diarrhœa resides ordinarily in the superficial layers of the earth, where it is intimately associated with the life processes of some microorganism not yet detected, captured, or isolated. That the vital manifesta-

tions of such organism are dependent, among other things, perhaps principally, upon conditions of season, and on the presence of dead organic matter, which is its pabulum. That, on occasion, such microorganism is capable of getting abroad from its primary habitat, the earth, and having become air-borne, obtains opportunity for fastening on non-living organic material, both as nidus and as pabulum, in undergoing various phases of its life history. That in food, inside of, as well as outside of the human body, such microorganism finds, especially at certain seasons, nidus and pabulum convenient for its development, multiplication, or evolution. That from food, as also from the contained organic matter of particular soils, such microorganism can manufacture, by the chemical changes wrought therein through certain of its life processes, a substance which is a virulent chemical poison; and that this chemical substance is in the human body the material cause of epidemic diarrhœa."

**A SOUVENIR.**—The Lambert Pharmacal Co., of St. Louis, distributed at the Newport meeting a very handsome little souvenir containing a list of the officers of the Association, programme of the general sessions, list of Presidents of the Association from 1846 to 1889, and a number of views of Newport.

**TRAINING SCHOOLS FOR NURSES.**—The seventh annual graduating exercises of the Illinois Training School was held at the County Hospital, Chicago, on the 25th ult. Addresses were made by Dr. J. S. Knox, Charles L. Hutchinson, President Brand, of the County Hospital medical staff, Franklin H. Head, Dr. Julia Holmes Smith, Dr. Sarah Hackett Stevenson, and Mrs. C. B. Lawrence. Diplomas were presented by Dr. Johnson to the following graduates: Abbie Brotherton, Mary L. Grott, Orissa Stanton, Lillian E. Beckley, Emma Baumbach, Ida F. Towers, Nora Morgan, Lizzie Glennie, Sara Krueger, Cora Overholt, Mary H. Porter, Lizzie M. Graham, May Bixby, Salome Beardsley, Hattie Sigsbee, Ellen Strandt, Carrie Keeler, Mary M. Roburn, Mattie Hirth, Dora Stager, Mary D. Sexton, Flora A. Reid, Anna Nicholes, Edna Goble, Laura Happerly, Idora Rose, Lillian Gilmore, Carrie Leoner, Nora Vasey, Emily Vasey, Emily J. Keisz, Ella Harth, Joanna Kellogg, Victoria King.

The Commencement Exercises of the Memphis, Tenn., Training School for Nurses was held in that city on the 23d ult. There were four graduates: Misses Effie Ingham, Hattie Dunlop, Lena C. Angevin, and Tillie J. Aiken.

**DIPHTHERIA AND THE SALOON BUSINESS.**—The Paterson, N. J., Board of Health has distinguished itself by a recent decision. It is to the effect that where the placing of a green card on a house to indicate the presence of diphtheria on the premises would interfere with the business of a saloon-keeper, the card may be placed on the back door, where the general public may not see it!

#### PAMPHLETS RECEIVED.

Transactions of the Medical Society of the State of New York, 1889.

Uterine Massage. By W. B. Sprague, M.D., Detroit, Mich. (Reprint.)

Observations in Clinical Therapeutics. By J. A. Robinson, M.D., Chicago. (Reprint.)

Annual Report of the Essex County Asylum for the Insane, Newark, N. J. 1889.

#### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from June 15, 1889, to June 21, 1889.*

By direction of the acting Secretary of War, the following changes in the stations of officers of the Medical Department are ordered:

Major Albert Hartsuff, Surgeon, is relieved from duty at Ft. Hamilton, N. Y., and ordered to Ft. Omaha, Neb.

Major J. M. Brown, Surgeon, relieved from duty at Ft. Omaha, Neb., and ordered to Ft. Meade, Dakota.

Capt. W. C. Shannon, Asst. Surgeon, relieved from Ft. Meade, Dak., and ordered to Ft. Yates, Dak.

First Lieut. Francis J. Ives, Asst. Surgeon, relieved from duty at Ft. D. A. Russell, Wyo., and ordered to Ft. Lyon, Col.

Capt. J. F. Philips, Asst. Surgeon, relieved from duty at Ft. Lyon, Col., and ordered to Ft. Crawford, Col.

First Lieut. Walter D. McCaw, Asst. Surgeon, relieved from duty at Ft. Crawford, Col., and ordered to Ft. McPherson, Atlanta, Ga. Par. 9, S. O. 136, A. G. O., Washington, D. C., June 13, 1889.

Capt. Robert J. Gibson, Asst. Surgeon U. S. A. (Ft. Trumbull, Conn.), is designated as medical officer for the encampment at Fisher's Island, N. Y., and he will proceed to Fisher's Island, N. Y., August 1, 1889, and report to the commanding officer for duty at that post. Par. 5, S. O. 133, Hdqrs. Div. of the Atlantic, June 13, 1889.

Capt. Walter W. R. Fisher, Asst. Surgeon, leave of absence for one month granted by S. O. 30, c. s., Dept. of California, and extended fifteen days by par. 3, S. O. 37 c. s., from these Hdqrs., is further extended fifteen days. Par. 1, S. O. 41, Hdqrs. Div. of the Pacific, San Francisco, Cal., June 12, 1889.

By direction of the acting Secretary of War, the following changes in the stations of officers of the Medical Dept. are ordered:

First Lieut. Benj. L. Ten Eyck, Asst. Surgeon (recently appointed), ordered to Ft. Leavenworth, Kan.

Capt. Jno. de B. W. Gardiner, Asst. Surgeon, relieved from duty at Ft. Leavenworth, Kan., and ordered to Ft. Reno, Ind. Ter.

Par. 3, S. O. 132, A. G. O., June 8, 1889, is amended so as to direct First Lieut. P. G. Wales, Asst. Surgeon, to report to Ft. Huachuca, Ariz., for duty in place of Presidio of San Francisco, Cal.

Capt. M. C. Wyeth, Asst. Surgeon, relieved from duty at Ft. Huachuca, Ariz., and ordered to Ft. McDowell, Ariz.

First Lieut. Leonard Wood, Asst. Surgeon, relieved from duty at Ft. McDowell, Ariz., and ordered to Presidio of San Francisco, Cal. Par. 2, S. O. 138, A. G. O., June 15, 1889.

First Lieut. Henry S. T. Harris, Asst. Surgeon, granted leave of absence for two months, by direction of the acting Secretary of War. Par. 13, S. O. 140, A. G. O., June 18, 1889.

#### EXTRACT.

By direction of the acting Secretary of War, the following changes in the stations of the Medical Department are ordered:

First Lieut. Benjamin L. Ten Eyck, Asst. Surgeon (recently appointed), will proceed from New York City to Ft. Leavenworth, Kan., and report for duty to the commanding officer of that post. Par. 2, S. O. 138, A. G. O., Washington, D. C., June 15, 1889.

#### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending June 22, 1889.*

Medical Inspector Grove S. Beardsley, granted a year's leave of absence, with permission to leave the United States.

Surgeon N. M. Ferebee, detached from special duty at Naval Academy, and wait orders.

Asst. Surgeon George Rothganger, ordered to the Naval Hospital at Mare Island, Cal.

ADDRESSES.

SURGICAL INTERFERENCE IN FRACTURES OF THE SPINE.

*Delivered in the Section on Surgery and Anatomy at the Fiftyeth Annual Meeting of the American Medical Association, June 25, 1889.*

BY N. P. DANDRIDGE, M.D.,

OF CINCINNATI, O. CHAIRMAN OF THE SECTION.

My first duty is to express my appreciation of the honor I have received in being selected to preside over the meetings of this Section. This honor brings with it, however, the embarrassing conviction that I lack many of the qualifications necessary and essential for properly carrying out the work for which I have been chosen. The ready co-operation that I have received in the effort to organize the work of the Section, and the great interest manifested in its success on all sides have contributed to make the experience of the past months among the pleasantest of my life, and I only trust that in looking back upon the completion of our meeting you may all be able to regard it with equal satisfaction. When I consider the characters of the papers you will listen to, and remember the prominence of their authors, and the large amount of learning and varied experience they represent, I may be excused for much misgiving as to my own ability to contribute anything which will be at all worthy of your consideration, and which will not suffer by comparison with the contribution of those whose opportunities have been so much wider than my own. Indeed, if I succeed in exciting your interest, and holding your attention, I fear it will be more from the importance of the subject itself rather than from anything of value I may be able to offer either in the way of original thought or in summing up the recorded work of others.

I have selected for my topic "Surgical Interference in Fractures of the Spine," and have been led to its selection partly by the fact that an unusual number of these injuries have fallen under my care during the last year, and will thus enable me from recent experience to present many of the salient features of the subject, and also largely from the fact that the recent achievements of Horsley, Macewen, Abbe, and others in this

field have opened up new avenues of progress, and have rendered it necessary to recast and revise conclusions which seem fixed on definite and legitimate foundations. Fresh impetus has certainly been given to active operative interference in all forms of spinal injury and disease, and while it is certainly true that the result of these new surgical triumphs must necessarily and properly enlarge our therapeutic resources in these most trying cases, it is also equally certain that without due regard for the recorded experience of the past we are likely to retard true progress by rash and unreasonable interference.

Indeed, if I mistake not, the indications are already apparent that operations upon the spinal canal will soon become popularized, and this one of the last of the great cavities of the body to be interfered with will become in the near future the frequent scene of either surgical success or failure. It is for this reason that I feel the time is opportune for a fresh discussion of the questions involved in determining the how, and the when, of surgical interference in fractures of the spine. In speaking of fracture it is to be understood that I make no sharp distinction between fracture and dislocation, but consider alike all forms of injury to the column resulting in more or less damage to the cord. Any conclusions which may be reached at this day must necessarily be provisional, for the date is not yet at hand by which we can definitely settle many of the points involved. I shall confine myself in this discussion to the question of active interference in fracture, but as the fresh impetus which has been given to work in this subject dates back to the successful removal of a spinal tumor by Horsley, and the operations for pressure symptoms in cases of Pott's disease by Macewen, it may be well to consider briefly how far these cases are analogous, and how far the deduction from one class can be safely applied to the other. In Horsley's case there was present all the symptoms of an advanced transverse lesion of the cord by which all power of conduction was abolished. This condition was due to a tumor which had produced an indentation, or depression, which penetrated almost through one lateral half of the cord. It should be recalled that this condition of the cord was due to a slowly increasing pressure—a

pressure which could not suddenly destroy the conducting tracks. The removal of this tumor was followed by a complete restoration of all the functions which had been lost.

In considering the question of operation for tumor, it must be remembered that removal is our only resource, and that we have no other method of treatment which promises any benefit whatever. In cases of Pott's disease the conditions in many respects are much the same, though they differ in some essentials. The narrowing of the canal by which pressure is made on the cord is not often due to simple changes in the bony walls, or to the acuteness of the angle caused by the curvature. It is generally due to the thickening of the membranes, the development of granulation tissue between the bones and dura, or to the accumulation of pus or other inflammatory products.

As a result of hæmorrhage or the penetration of the canal by an abscess pressure symptoms may be suddenly developed. But in all these cases the compressing body is of such a nature that the elements of the cord are not divided, but their vitality is slowly or suddenly compromised by interference with nutrition or by secondary degeneration. The resulting condition may be exactly the same as in the case of tumor or fracture—paralysis below the point of pressure more or less complete—exaggeration or loss of reflexes—retention or incontinence of urine and feces, and the ready occurrence of bed sores and other trophic changes; but while the symptoms present may be exactly the same as in the case of tumor and due to a compressing body, the question of treatment is one which occupies an entirely different position. In the case of tumor without operation we are entirely powerless—in Pott's disease it is otherwise, for it is a matter of daily experience that the most serious and threatening symptoms may disappear spontaneously. Sensation and motion are both often rapidly recovered after the application of the plaster jacket, or following the administration of the iodide of potash. But in certain of these cases the organization of the inflammatory products, and the thickening of tissue reaches such a degree that they may be fairly compared to a tumor growth and quite beyond the reach of removal except by the knife. Charcot has demonstrated that this condition is most apt to occur opposite the point of greatest curvature in the spinal canal. In such cases Macewen has first shown that operative interference may be followed by most brilliant results where the conditions are apparently helpless, and where continued treatment of various kinds has been entirely without success.

In the second case he reports after removal of the lamina he found a connective tissue tumor so closely adherent to the dura that a part of that membrane was removed with it. The cord was

compressed to one-half its normal size, but on removal of pressure began to pulsate, and within a few hours there was notable improvement in the warmth and lividity of the limbs. This patient regained entire use of the limbs after the existence of paralysis lasting over eight months.

It will be of interest in this connection to examine the results obtained in cases of resection already reported. Ten cases are available for this purpose. Unfortunately many of the cases are so imperfectly recorded that their value is greatly diminished. Certain positive facts of value can, however, be determined. Mr. Horsley in a recent letter reports restoration of power after complete paralysis for six or seven years. In Macewen's first case paraplegia of two years' standing with bed sores and incontinence was entirely relieved by the removal of the arches of the fifth, sixth and seventh dorsal vertebræ. These cases have an important bearing on the subject we are discussing, and are in themselves a partial answer to the argument advanced for early operation—that delay will necessarily compromise all chances of success. They certainly show that the cord after long continued compression, severe enough to abolish all conducting power may, by relief of pressure, again recover its functions. Trephining the spinal column in Pott's disease does not seem to be a very serious operation. Out of the ten cases one died in twenty-four hours, one in a week, and one of general tuberculosis in seven months. It certainly promises a field of usefulness in properly selected cases, and will, I believe, rescue some where all other means would prove unavailing. The danger is that many patients will be subjected to the trephine in whom slower and less brilliant forms of treatment would produce better results with less danger of disastrous consequences. In this connection it is a matter of interest and importance to determine after what length of time we must give up all hope of the disappearance of paraplegia in Pott's disease. I desire to place on record a case bearing on this point, in which after complete paraplegia for more than three years and a half voluntary power returned, and six months later the child was able to walk with a slight support. This child, now 7 years old, has been under continuous observation for over four years at the Children's Hospital, Cincinnati, with marked curvature in the upper dorsal region. On admission there was complete loss of power in both lower extremities, but neither incontinence nor bed-sores. This condition continued without improvement until six months ago when motion began to appear at first in the thigh muscles, and now he is able to stand, and with slight aid to walk. The improvement has been continuous and complete restoration seems probable. For nearly two years the treatment has been a little more than proper nourishment and good hygienic surround-

ings. The case has made a deep impression on my mind as showing the power of recuperation possessed by the cord.

Let us now consider how far the lesions present in fractures are similar to those we have just been considering. In fractures of the bodies of the vertebræ with displacement the antero-posterior diameter of the canal may be narrowed in any degree up to complete obliteration, and the cord may be injured in any degree up to a complete division—the membranes being either contused and lacerated, or entirely uninjured. It is stated by Hutchinson that direct compression of the cord by displaced bone is not often seen at the autopsy in these cases. This is due to the fact that the greatest amount of displacement is momentary, and that correction is effected in the subsequent removal and handling of the patient. In fractures involving the lamina the bone may or may not be depressed sufficiently to make pressure on the cord. Extra or intradural extravasation of blood, or hæmorrhage into the cord itself may occur as the immediate result of injury to the column without any evidence of displacement being present. Within a few weeks a case illustrating this fact has come under my care.

*Case 1.*—An adult fell backward from a ladder a distance of five or six feet, and struck on the back of his head; when seen in the hospital he was evidently much stunned though not unconscious. He was able to move all four extremities—the limits of sensation could not, however, be determined. The pulse was quick and small, the breathing hurried and shallow, and the face somewhat flushed. Movement of the head caused pain, particularly in flexion. No deformity could be detected in the spine. When seen in the evening the breathing was rapid, and almost entirely abdominal, and the face deeply flushed; movement in the extremities still existed. Death occurred eighteen hours after the accident. At the post-mortem examination a partial dislocation forward of the second cervical vertebra was found with slight displacement. The spinal canal was laid open from behind—the cervical arches were intact, the membranes were untorn and normal, and on laying them open no evidence of injury to the cord could be seen as it lay in the spinal canal. The cord was removed, and when laid on the table presented no evidence of injury until by passing the finger along its surface a transverse section of softening corresponding to the height of the displaced vertebra was discovered. The cord was now divided by a longitudinal antero-posterior section. Slight softening involved the entire thickness of the cord, and within this area on either side a small clot of recently extravasated blood was found. These clots were found on either side of the central canal, and were so centrally situated that on the surface of the cord

there was no evidence of their existence. The persistence of motor power in the four extremities showed certainly that these lesions had not entirely destroyed the conducting power of the cord. The cause of death must have been due to interference with the origin of the phrenic nerve. In a less vital portion of the cord there is no reason why such a lesion should have suddenly terminated life, and it seems not unreasonable to suppose that complete restoration of function might have followed absorption of the clots, and it is not improbable that in cases of recovery after paralysis in spinal injury, such lesions may frequently exist. Repair under such circumstances will certainly not be aided by any operative interference. The changes which follow fracture may result in thickening of the membranes and the production of more or less inflammatory tissue, or pus within the spinal canal, sufficient to cause marked pressure on the cord—a pressure which in some cases may explain the continuance, or reappearance, of the paralytic or trophic symptoms. These cases then approximate the condition found in Pott's disease, suffering from pressure symptoms, plus the amount of the original, and unrepaired damage to the cord itself. The question of operative interference in spinal injury must be considered in reference to interference immediately after the receipt of injury, and interference deferred until the amount and character of permanent disability can be determined. The solution of these questions involves a consideration of the course and results of fracture treated without recourse to operation. It is well known that not only a considerable number of these cases escape death, but entirely recover all their functions, even after the existence of paralysis, incontinence, and bed-sores existing for a variable length of time. In a valuable paper Burrill has investigated the results of all the cases which have occurred in the Boston City Hospital—eighty-two cases in all—of which eighteen survived. Divided into regions we find twenty-eight cases of fracture of the cervical vertebrae gave two recoveries—twelve cases of fracture of upper dorsal vertebrae, six recoveries—nineteen cases of fracture of lower dorsal, one recovery—twenty-three cases of fracture of lumbar vertebrae, ten recoveries. Of the sixty-four fatal cases thirty-five died within five days—eight from five to ten days, and seven in from ten days to one month. Five of these cases were submitted to operation—all of which were promptly fatal. In the eighteen who survived the result was good in nine, and in nine complete disability remained permanent. The especial value of Burrill's paper is that it is based on the entire number of cases treated in a single institution, and gives, therefore, more reliable data for deductions, than statistics made up of isolated cases. Favorable results always obtain undue prominence under

such circumstances. It is apparent from the above figures that 21 per cent. of fractures of the spine survive, and that over 10 per cent. make a satisfactory recovery.

Of the fatal cases a very large proportion die in the first few days—a fact of importance in estimating the danger of operation, the high mortality of which in cases of recent injury can not properly be attributed to the operation itself, but is largely due to the concomitant injury.

It is further evident that while treatment is successful in preserving the lives of a considerable number, one-half the survivors are left completely disabled, so that any addition to our therapeutic resources must be eagerly welcomed. I can best present the points involved in the question of treatment of spinal fracture by briefly referring to the more salient features of the cases which have come under my care in the last few months, and describing the methods adopted in each and the results obtained.

In addition to the case of dislocation above reported I have had in the time specified five cases of fracture of the dorsal spine; in three of these cases the plaster jacket was applied within a short time of the accident, and in two the result was entirely satisfactory, but in the third only partially so—in one an air-bed was used with persistence of the paralysis and incontinence and the development of extensive bed-sores. This case at the end of five months was trephined—the 10th, 11th and 12th dorsal and first lumbar arches removed. The last case was treated on an ordinary bed, great care being exercised to avoid pressure, and at the end of several months had gained control of bladder and rectum, complete restoration of sensation, and improvement of motor power. The disabilities which remained were markedly improved by systematic suspension several months later.

*Case 2.*—An adult, as the result of forcible bending of the body in driving under a low archway, suffered a fracture of the spinous process of the 11th dorsal vertebra, which could be felt movable and somewhat displaced under the skin. There was no paralysis of motion or sensation or any disturbance of the function of the bladder or rectum. Every movement of the body was painful and there was entire inability to sit up in bed. A plaster jacket was at once applied by means of the hammock suspension and was followed by immediate relief of pain and by ability to move about and sit up in bed. In five weeks the patient walked out of the hospital quite well.

*Case 3.*—A carpenter fell 25 feet from a scaffold, striking his back; the fall produced at once complete paraplegia. He came into the hospital three or four days later. Paralysis of motion and sensation was complete nearly to a level with the umbilicus, and there was retention of urine. The fourth and fifth dorsal spine were slightly promi-

nent and were painful on pressure, and movement of the body caused pain in this part of the column. The jacket was applied in the hammock at once, and immediately gave a great deal of comfort, enabling the patient to move in bed and sit up without pain. For seven or eight weeks it was necessary to use the catheter, when expulsive power was regained and the pus and mucus disappeared. During the first few weeks the bowels were only moved by injection. Sensation began to appear in the lower extremities after seven or eight weeks and was soon followed by voluntary motion. This improvement continued and in eighteen weeks the man was able to walk. Six months later there remained only a slightly ataxic gait and the man was able to resume work as a carpenter.

In one other case the jacket was applied on the fifth day after fracture in the lower dorsal region. At this time there was paralysis in both lower extremities, retention of urine and involuntary escape of feces. The jacket afforded comfortable support. Within a few weeks a bed-sore developed over the sacrum and incontinence of urine and cystitis followed. In four months sensation had completely returned, the thigh muscles could be voluntarily moved, but there still remained paralysis of the legs, and the incontinence was as bad as ever and has continued up to the present time unimproved.

The application of a plaster jacket in the treatment of fracture of the spine is certainly no novelty, as many cases have been reported and its use has materially improved the ultimate results as well as adding greatly to the immediate comfort of the patient. The method of application I regard as of great importance, and sufficient appreciation, has not, I think, been shown to the use of the hammock suspension, as first suggested by Mr. Davy. An extensive experience in the use of the hammock in the application of the plaster jacket for Pott's disease has given me great confidence in this method wherever a spinal support is required, and in cases of fracture it presents special advantage. In a case described by Burrill, in which suspension was employed, the pain is described as so agonizing that the jacket was completed with great difficulty, and I cannot but think that there must be at times danger where the continuity of the column has not been impaired. One advantage only I can see that suspension can possess over the hammock, and that is that the weight of the body may act as an extending force in overcoming any displacement. In Burrill's case sensation was felt in the toes the moment the body was free from the bed. But extension can be perfectly well practiced with the hammock, and the further advantage of an anæsthetic can be obtained with safety while the patient remains in a horizontal position.

The method of using the hammock is very sim-

ple; a piece of strong muslin as wide as the patient's body and about 15 feet long is stretched out on the bed beside him, a proper undershirt is applied and the patient is gently rolled over until he lies prone on the hammock. One end is now securely knotted to a strong hook in the wall and the other end attached by a pulley to a fixed point at the opposite side of the room and the patient is then swung free from the bed. After protecting the bony points, the plaster bandages are applied including the hammock, and the suspension continues without any inconvenience to the patient until the jacket is perfectly hard. In none of the cases in which this method has been used has there been any pain complained of, and in one of the fractures the patient compared it most favorably with the discomfort of a former suspension.

In one case, still under observation, decided benefit has been obtained in improving the condition some months after fracture by systematic suspension.

*Case 4.*—An adult, æt. 30, carpenter, fell 30 feet, striking his back and producing complete paraplegia—motion and sensation being both abolished. For five weeks it was necessary to use the catheter, when expulsive power returned; for about the same length of time the rectum was evacuated only by the use of injections. Cystitis soon developed, bed-sores occurred on the heels and over the right trochanter. In six months he had so far improved that complete control of the bladder and rectum was regained. Sensation throughout returned and there was marked improvement in motion. In the right leg there was fair control of the thigh muscles; in the left scarcely any voluntary motion at all. There was no voluntary motion in leg or foot muscles on either side. The reflexes were greatly exaggerated and contact of feet with the floor or slight tapping of the finger over thigh or patella produced such violent contractions of all the extensors of the leg that the knees could not be flexed for some minutes. At this time a marked curvature in the lower dorsal region, the prominence involving several vertebrae, and in this condition he was admitted to the Cincinnati Hospital, for the purpose of trying suspension. He was suspended twice daily, at first for five minutes at a time, and then the time was much lengthened. The benefit was evident from the first. The exaggeration of the reflexes soon showed diminution in intensity and there was improvement in voluntary motion.

The treatment still continues and it is too soon to determine the ultimate result, but thus far the patient's condition seems to show that we have in suspension the means of further improvement where recovery has fallen short of complete success. The range of its usefulness can only be determined by further trial. This method of treatment is still so new that it is not worth while

to speculate on the manner in which suspension acts. It may, however, be suggested that repair in fracture of the vertebrae often falls short of complete bony union, and in these cases a suspension may possibly act by straightening the canal and thus relieving pressure.

In the admirably analyzed tables of fracture of the spine in Ashurst's essay the great advantage of immediate correction of the deformity and displacement by extension and manipulation where the cervical vertebrae are the seat of injury is prominently enforced, and later experience has fully confirmed the conclusions of the author in this respect, so that the benefit of this practice may be considered so fully established that it does not require further argument to support it.

I have had one case in which I have trephined the spine and removed the 10th, 11th, and 12th dorsal, and first lumbar arch. The operation was undertaken five months after fracture in the dorso-lumbar region. There was present at the time extensive bed-sores, incontinence of feces and urine and complete paraplegia.

*Case 5.*—F. H., æt. 27, entered Cincinnati Hospital November 1, 1888. Four days before he fell through a hatchway and found himself unable to rise. On admission there was complete paralysis of motion and absence of sensation as high as the crests of ilia, and inability to void urine. Incontinence developed within a few days, with involuntary discharge of feces. The patient was at once placed on an air-bed, but in spite of the most assiduous attention cystitis developed and extensive bed-sores appeared over the sacrum and along the posterior aspect of both legs within two or three months. Sensation returned to the middle of the thighs, but there was no improvement in motion. On return to hospital service, April 1st, five months after the accident, I found no further improvement, but on the contrary spreading bed-sores and the cystitis, incontinence and paralysis unchanged. The operation of exsection was explained to the patient, and the possible chance of benefit which it offered, and after consultation with his friends he decided to accept it. April 10th, with the assistance of the surgical staff of the hospital, the spinal canal was opened. A free incision was made over the spinous processes, the center of which was the 11th dorsal, and the muscles were rapidly dissected off, so as to fully expose the lamina on either side; bleeding was controlled by packing the wound with sponges. The spinous process of the 12th dorsal was first cut away with strong cutting forceps and the trephine then applied and the canal opened. The arch of the 11th dorsal and first lumbar was similarly removed. The dura thus fully exposed was covered with a thin layer of rather closely adherent connective tissue, which was scraped away with a blunt spoon; no pulsation was seen and the cord appeared normal to the touch, except at the upper

part exposed, where it seemed diminished in consistency, and as the membrane appeared closely applied to the arch above this was also removed. No condition causing compression was discovered, and the dura was not opened. The wound was closed throughout, except at the lower end, where a large drainage-tube was inserted, reaching to the bottom of the cavity, and a voluminous dressing of gauze and absorbent cotton applied. The following day this was saturated through by the discharges and was renewed; on the fourth day the dressing was again changed, and as the discharge was small the drainage-tube was removed. This I am now satisfied was a mistake, and I attribute the suppurative which occurred and the delay in healing of this part of the wound to this fact. Except about the tube the wound healed by first intention. For several days there was slight fever and the bed-sore over the sacrum increased slightly from a slough. Eight weeks after the operation the wound was entirely healed. The general condition was certainly better, the urine was almost perfectly clear and of acid reaction, and some of the bed-sores were entirely healed, and all improved and contracted. Incontinence still persisted, and there had been no improvement in either sensation or motion. So far as the operation is concerned I consider that it has been entirely negative, and that the improvement which has ensued has been due to the assiduous care and attention the man has received. This result, however, I do not feel should discourage further effort under proper conditions. Indeed, earlier operation I believe is indicated, and sufficient success has been attained by others to more than justify further effort in the surgical interference in these cases.

The operation is not difficult, and is now shown to be not very dangerous, and where continued treatment has failed to afford relief resection should be undertaken without very great delay, for even where complete success has not been attained the operation appears to have a marked influence in controlling cystitis and incontinence, and in hastening the healing of the bed-sores, results which amply compensate for the small amount of danger. Ashurst, in the essay referred to, has presented the result of resection of the spine up to that time, and asserts that there is "no well authenticated case of cure after the operation when undertaken for fracture." Surgical writers previous to the reports of Horsley and Macewen are unusually unanimous in condemning the operation. Among the latest, Page, in Heath's Dictionary, says that "it is an operation not within the range of practical surgery." To this general pessimistic view Erichson is a notable exception, and largely on the result of Gordon's case in Dublin advocates further trial. In this case sixty-seven days after injury the arches of the 12th dorsal and first lumbar vertebrae were removed for

fracture of the lamina of the latter. The operation was undertaken for the relief of incontinence and cystitis, complete paraplegia and extensive bed-sores, and resulted in much benefit. The cystitis disappeared, entire control of the bladder was regained, the bed-sores healed, sensation returned, and the paralysis of motion was greatly improved.

Since the appearance of Horsley's paper I find 10 cases of trephining the spine for fracture. Many of these cases are most unsatisfactorily reported, but several points of importance and interest may be gathered from them. Macewen reports a case, operated on five weeks after accident, in which the 12th dorsal and first lumbar arch were removed, the former being fractured, and complete success obtained. Horsley removed the 11th and 12th dorsal after the appearance of bed-sores, with marked benefit to the patient, but without the complete disappearance of motor paralysis. In no case in which operation has been performed within a few hours of injury have I been able to find a complete success reported. Most of the patients have lived, some slight improvement noted, but in none has there been a disappearance of the paralytic symptoms. In determining the propriety of immediate operation the question may be asked whether in fracture of the bodies of the vertebrae removal of the arches and the severance of the ligaments must not necessarily further weaken the column as a whole, and so render displacement more liable to occur. Such an objection would not exist after partial or complete consolidation.

In all cases where decided benefit has followed fracture of the arch only has been reported. It has been urged that where fracture of the body is present, with the narrowing of the canal, that removal of the lamina will permit the cord to expand backward. I have not been able to find recorded any case where this has been demonstrated.

Experience is now rapidly accumulating, however, in these cases, and may soon fully confirm these suggestions. As for technique of the operation Horsley's description is so complete that little can be added. The condition demanding the opening of the dura requires investigation. Such a step adds to the gravity of the operation, but failing to do so in some cases may possibly account for want of success. The conclusion to which this discussion points is this: that in injury to the spinal column with the symptoms indicating damage to the cord, experience has already shown that a satisfactory result may be obtained in a considerable proportion of cases, and that in the majority of those that recover after the existence of paralysis, retention or incontinence, improvement only begins after some weeks, or possibly after some months. Recent experience has certainly shown that resection of the spinal arches is not so

dangerous or difficult as was once supposed, and, furthermore, that it is capable of dealing successfully with cases of pressure on the cord of long duration after other methods have completely failed. It is certain, therefore, that we have in operation an additional resource in fractures of the spine. I cannot but feel, however, that the tendency at present is to push to an extreme the analogy between tumor and Pott's disease producing symptoms of paraplegia, and cases of fracture, in determining the question of operative interference where the symptoms do not yield at once to a correction of the displacement, is likely to result less satisfactorily than trusting to the other methods longer in use. At the same time a sufficient number of cases exist to show that under certain conditions resection will save life and remove symptoms worse than death itself.

From the above I feel justified in presenting the following provisional conclusions from which doubtless many will dissent:

1. In fractures of the cervical vertebræ there is indicated immediate reduction of any displacement by extension and manipulation under an anæsthetic, followed by continuous extension and immobilization.
2. In all fractures of the dorsal or lumbar spine involving the bodies or the arches, with or without evidence of injury to the cord, the immediate application of the plaster jacket by the hammock suspension preceded, if there is evident displacement by an extension, under an anæsthetic.
3. When symptoms indicating injury to the cord persist without improvement resection is indicated.
4. Immediate operation would be indicated where there is marked depression of the arches with symptoms of paralysis.
5. Long continuance of the symptoms is not in itself a contraindication to operation.
6. We have in suspension the means of alleviating some of the sequelæ of fracture of the spine.

## POPULAR PROGRESS IN STATE MEDICINE.

*Delivered in Section on State Medicine at the Fiftieth Annual Meeting of the American Medical Association, June 25, 1889.*

BY J. BERRIEN LINDSLEY, M.D.,

OF NASHVILLE, TENN., CHAIRMAN OF THE SECTION.

The Section on State Medicine has two feet upon which it securely stands—law and science. My immediate predecessors as Chairman of the Section have noted the recent progress in science as connected with its practical work. On this occasion I shall, with great brevity, note progress in the other direction. As in America all law depends upon the sovereign will of the people, who are at once governors and governed, my topic is

substantially "Popular Progress in State Medicine."

This progress is one of the great features of the present century, which is as signally characterized by the application of the physical forces to the daily uses of man as was the fifteenth by the unfolding of the globe's map. Thirty years ago sanitary ideas, problems, reforms and work were unknown, or at all events unmentioned. To-day, outside of partisan politics with its perquisites, no topics engross so large a share of public attention as do those belonging to practical sanitation.

As evidence of the recent and rapid progress State Medicine has made in the United States, the following substantial proofs may be cited:

### STATE BOARDS OF HEALTH.

The first State Board of Health created was that of Massachusetts, at a date no longer ago than 1869. From a table very carefully compiled by Dr. Geo. Homan, Secretary of the State Board of Health of Missouri, we learn that, in 1888, twenty-nine States maintained Boards of Health, by an annual expenditure of more than half a million dollars. Thus a major portion of the American people are becoming acquainted with the connection between law and health.

In most instances these Boards have high powers. In all cases they exercise a great educational influence.

Voluminous reports, prepared with care, and with special adaptation to the several localities, are liberally distributed. At this date the series issued by those two advanced States, Massachusetts and Michigan, constitute a cyclopædic collection of treatises upon all the pressing questions of public sanitation. The Illinois Board has exerted a lasting influence upon medical education by its persistent efforts to protect the people from imposition. Perhaps it is not beyond fact to say that a very few years of legal effort by this single State Board has done more to elevate medical education than all the advisory and hortatory resolutions of our own great Association in forty years. Law is a rapid and efficient educator. No less than eight of these twenty-nine State Boards issue monthly publications containing reports and information from all localities within their bounds. These periodicals are circulated by the thousand, and tend materially to advance the work. All date within the last four years.

### CITY AND LOCAL BOARDS.

The progress, influence, powers and expenditures of city Boards of Health in the recent decade is even more remarkable than in the case of State Boards. I have not at hand such an analysis of their work as that furnished by Dr. Homan, above referred to. However, a single topic under their care reveals the wide scope of their functions and the immense results which must in a few years

ensue. Healthy homes for all the people is becoming their watchword and the demand of their constituencies. To exemplify this point time forbids. The work done by the New York, Boston and Nashville Boards may be cited in proof.

A wonderful illustration happened in Europe only a few days ago (June 15), when the King, Queen and Crown Prince of Italy inaugurated the improvement of the sanitary condition of Rome. This grand work will require ten years for its completion. Many new streets will be opened and 17,000 houses be demolished.

The American Democracy long since voted itself public schools by means of which the keys of knowledge are placed in the hands of all. Witness Massachusetts, which for its last scholastic year voted without grudging the royal sum of \$7,500,000.

The American Democracy will beyond a doubt, long before the next century becomes old, vote that each man, woman and child of its many millions, everywhere upon its imperial domain, shall breathe the pure air of heaven and enjoy that bright sunshine which is the truest emblem of the Divine Giver of all life.

Ever since my student days in that loved Alma Mater, the glorious old University of Pennsylvania, have I, as opportunity offered, inspected the dwellings of the masses in our large cities, and always with sadness and compassion, that so many among them fared no better than like classes in the Old World. Now, when these scenes meet my eyes, it is with the comforting reflection that such disgraces upon our vaunted civilization will soon pass away.

#### VOLUNTARY ASSOCIATIONS.

These are rapidly becoming a power. On April 18, 1872, in the rooms of the New York City Board of Health, seven pioneers founded the American Public Health Association, which now counts its membership by the hundreds. This Association has published fourteen substantial and handsome volumes, permanent memorials of the best thoughts of very many of the most eminent practical sanitarians in America. By the thoughtful liberality of a single member, Mr. Henry Lomb, of Rochester, N. Y., it has sent many thousand copies of capital essays among classes specially needing and prizing such instruction.

The Newport Sanitary Protection Association is a model in its way, which in a very few years will be widely copied in all parts of our great Republic.

The New York Ladies' Sanitary Association, recently formed, has some 350 members. It has taken hold of such great subjects as defects in public school buildings, the removal of garbage, and the like. Though in its infancy, it is already noted for good work.

#### INCREASED RESPECT BY RULERS.

This is very remarkable, and has done much to give our cause prestige with the people. The sayings of D'Israeli the gifted, and of other eminent British statesmen, have become axioms. No greater tribute, however, has ever been paid to State preventive medicine than the idea recently advanced by an American Secretary of State, looking to the peaceable acquisition of a great island now a plague-spot, a terror and a menace to our people, that so it may come under the redeeming influence of sanitary science.

#### THE BARRING OUT OF CHOLERA.

In 1884 and 1885 France, Spain and Italy were visited by an epidemic of Asiatic cholera which alarmed all Europe, and created great uneasiness in our own country, specially in the vast Interior Valley. In all previous visitations of this exotic pest it was allowed free course. On this occasion, however, it was met by the organized hosts of scientific physicians acting with the power of law, and was stopped short in its career. This fact has given the American public great respect for and great confidence in State preventive medicine, as I know from conversing with many outside our profession.

#### GREAT MONEYED INTERESTS AROUSED.

Yellow fever epidemics, and even yellow fever scares, are now of National importance because of their disastrous influence upon inter-State commerce. The scare of last year damaged more or less all the railway companies with extensive lines in the South, probably more than the really great epidemic of 1878, which was so fatal to life. This because of the increase in mileage of these railroads. During the continuance of this scare and consequent embargo upon commerce, very many railroad and mercantile men studied and discussed the perplexing topic of quarantine. These men represented millions upon millions of capital and multiplied thousands of employes. One sentiment prevailed among them, respect for State Boards, abhorrence of local shot-gun quarantines, and a desire for a central Federal head at Washington which should coöperate with State Boards and harmonize quarantine rules. There are no better auxiliaries in public health work in the South than our railroad officials. The depopulation of Decatur, Ala., when yellow fever was declared epidemic, as conducted by the management of the Louisville and Nashville Railroad, was a model for promptness, efficiency and humanity.

The recent astounding calamity of May 31, in Pennsylvania, has also awakened a widespread feeling of the necessity of a Federal hand which in such unexpected and destructive calamities shall be ready to aid local authorities with that promptness and wealth which great Governments alone can exhibit. In such times of trouble there

should be no necessity for the slow, uncertain and costly agency of voluntary contributions from individuals among 65,000,000. Our Government is a Commonwealth of States, and at its Capital has all the organization for mutual insurance against earthquakes, floods, and pan-epidemic pestilence that can possibly be needed.

#### LIFE INSURANCE AND VITAL STATISTICS AND SANITATION.

As it respects numbers interested and capital involved, life insurance is second to no business in America. Without vital statistics it walks in darkness. With local sanitation it is intimately concerned. A company at Hartford has within ten years sent an accomplished physician twice to Tennessee on an inspecting tour, whose reports give an admirable summary of the sanitary condition of that State, though never published. This kind of inspection is more frequent than health officers are aware. It is impartial and meant for business uses alone. Unhealthy countries are embargoed by life insurance companies, for a single epidemic may destroy the resources of years.

#### THE BUSINESS INTERESTS OF AMERICA NOW DEMAND THE UNITED STATES PUBLIC HEALTH SERVICE.

This topic for twenty years past has been much discussed in medical associations, National and State; also in sanitary conventions of all kinds. Various plans have been proposed with widely different features. At one time, 1879, a National Board of Health was created, from which much was expected. These expectations were disappointed, and perhaps inevitably, since this Board was not in harmony with the machinery of the United States Government. Perhaps, also, because it was mainly established under the spur of an epidemic disease which affected only one section of the Union and did not concern the people of more than half the States.

Every one conversant with the development of bureaus and departments at Washington is aware of the fact that in each instance they are the outgrowth of progress in the separate States, and of the wants of large classes of people.

After many States had created agricultural bureaus, boards or commissioners, and after the farmers had become widely interested in the matter, Congress enacted a Bureau of Agriculture. After a while this was exalted into a Department, without a seat in the President's Cabinet council. Very recently it has made the last step in advancement, and its head is a full Cabinet minister. Nearly all the States had systems of public schools before the Bureau of Education was created, which, under the long and successful administration of Commissioner Eaton, passed from infancy to vigorous manhood. This Bureau works in perfect harmony with the State Superintendents of Public Instruc-

tion. It gathers, arranges and collates a vast amount of educational statistics and information not coming under State purview. It represents the vast corps of teachers in the Union at Washington, increases the self-respect of this large body of influential citizens and, as a consequence, grows continually stronger in the public esteem.

There is now at Washington nearly all the provision or machinery of a Health Department worthy this mighty people, which yet does not satisfy the public demand for want of enlargement and coördination. A service nearly a century old, established originally as an act of charity to a heedless class, and supported by a tax upon that class, has, by a singularly interesting process of evolution, expanded into a Bureau with four exceedingly important drawers. The care of the United States Marine Hospitals, once its sole function and the cause of its creation, is now only one of its duties, a great charity though it be, with a chain of splendid buildings perfectly equipped and ably managed. All honor to him who conceived the idea of elevating this service from the low estate into which partisan administration had reduced it. All honor to those who have changed it from sinecure posts for party reward to scientific positions for genuine merit.

Last year, in pursuance with an earnest request from the American Medical Association, Congress greatly enlarged the ability of this Service to take charge of maritime quarantine, so that now this, one of the chief functions of a National Health Bureau, is by common consent placed in its hands, with funds and powers amply sufficient for most efficient work. Surely this addendum far outweighs in importance and esteem its moderate hospital work.

Curiously enough, last year also a threatened epidemic of yellow fever brought a demand upon the central Government for assistance which could not be refused, inasmuch as a contingent fund for just such purposes had been placed to the order of the President, who could find no other channel through which to extend relief than this same old seaman's friend. Thus inter-State quarantine and aid fell under its wing. And though this may be a temporary work, yet when occasion does occur for its performance, in magnitude and importance it dwarfs even maritime quarantine. A fourth drawer in this nondescript Bureau is the direction of investigations throwing light upon the causes and prevention of diseases, which has been committed to its charge in more than one instance by Act of Congress during the few years just passed.

Thus it would seem that the United States Marine Hospital Service has altogether outgrown its name. It should be styled the United States Public Health Service, while retaining essentially its present organization. Maritime quarantine, inter-State quarantine and aid, and scientific researches, with its original work should constitute

four separate sub-departments with ample funds and full clerical force. The head of the whole should be, as now, a Supervising Surgeon-General. This is better than a Bureau with a political appointee at its head. The term Service is significant and it is popular.

The U. S. Signal Service, Life Saving Service, Light Service, are doing much to render the Government revered as a benefactor instead of being regarded as a harsh tax-gatherer. The small sum expended upon lights along both banks of the Mississippi River has done more to lighten toil, mitigate danger and save loss of life and property, than immense sums expended in other channels.

The United States Public Health Service thus established, by a process not of revolution but evolution, can be most efficiently aided in its wide field of action by three existing agencies at Washington, each of which has been long in operation with universal favor and popular support.

*First.* The United States Signal Service. Climatology is of late admitted by all to be a most important branch in the study of preventive medicine. It will not be long before weather warnings will be more in request for health purposes than even now for commercial and agricultural reasons. One or two clerks in the Public Health Service can obtain and coördinate all the weather knowledge it may need as effectually as if the two Services were combined in one.

*Second.* The United States Census Bureau of Vital Statistics. Every ten years the Government, in connection with the enumeration of the people required by our polity of representation, sets to work a Supervisor of Mortality and Vital Statistics for that special census. This office should be permanent and the work continuous. All admit the supreme importance of accurate vital statistics as the very basis of practical sanitation. The experience of over a century shows that the States and Territories will not efficiently provide these statistics. A few large and wealthy States may, but, judging the future from the past, the youngest grandchild of our great-grandchildren will not live to see America on a par with Great Britain in this, the very basis of a high civilization. This work is eminently within the province of the Federal Government, and will find with the people a welcome not less warm than that extended to the postal or weather services.

*Third.* The United States Coast and Geodetic Survey. A minute topographical survey is an essential in sanitary work. Great Britain, France, and even Spain, a country which we ignorantly much underrate, have either perfected or are perfecting topographical maps on a scale of several inches to the mile. These maps are perfect delineations of the country. In America there is not a single State thus mapped, and perhaps never will be. It is a costly work, requiring time and

highest scientific skill. This, too, is eminently an undertaking for the Federal Government, of absolute necessity from a military standpoint no less than for public health reasons.

That a complete Weather Service in each State under the control and support of the United States; that the permanent collection, collation and publication of the vital and mortuary statistics of each State under the same authority; and that a minute topographical survey of each square mile in the three and a half millions over which floats our flag, is also its legitimate work, follows logically from the fact that each and all of these great factors in the people's progress to a civilization higher than any which has yet been attained by humanity, are eminently National in their character and relations; and also from the further fact that their cost is far beyond the means at the disposal of the States. Be it always remembered that the States have surrendered to the Federal Government the two lucrative sources of revenue, customs and excise duties, and thus left themselves poor.

Above is briefly sketched the outline of a plan which, without jostling or jarring, but simply by expansion and coördination, will give what the American Medical Association has so often and earnestly demanded—a Public Health Service worthy our Continental Republic, which, though but a century old, already rivals in influence, fame and future hopes the mighty Republic of antiquity whose name is even now a synonym for dominion.

### NOTE ON SOME GYNECIC USES OF BORIC ACID.

*Read in the Section on Obstetrics and Gynecology, at the Fortieth Annual Meeting of the American Medical Association, June 25, 1889.*

BY WILLIAM WARREN POTTER, M.D.,  
OF BUFFALO, N. Y.

It is simply proposed at this time to record some personal experiences with boric acid in gynecological work. This will necessitate a tolerably free employment of the personal pronoun, for which I trust your pardon will be readily granted.

I was first led to the use of this agent in the manner detailed, in casting about for a substitute for iodoform. After using the latter drug twelve years, surgically and gynecologically, in sundry and divers ways, I was compelled to abandon it by reason of a poisonous effect it produced on my hands. This was a sore grievance, for it seemed at the time as if it meant the relinquishment of my work to a considerable extent. Whenever I suspended the use of iodoform my hands recovered, but every time I took it up again a derma-

titis was set up, and exfoliation of the cuticle followed.

In boxing the compass for a substitute that should stand completely in its stead, no little difficulty was experienced, for I must needs have one that would answer both aseptic and antiseptic indications. To be sure, I knew something about boric acid and some of its various uses in medicine and surgery, but it did not readily occur to me to make such use of it as I had previously done of iodoform—not, indeed, until I had tried several other drugs that, one and all, only served me indifferently well.

In the treatment of the various uterine and ovarian displacements it had been my custom in many instances, for some years, to pack the vagina in one way and another with cotton, wool, and other materials, first dusting the vaginal surfaces with iodoform in the dry treatment, or saturating the first two or three pledgets in glycerole or iodoform if the moist packing was employed. Experience had taught me that in this way I could make the packing last much longer without decomposition of the uterine and vaginal discharges—a desideratum of no inconsiderable importance. But without iodoform I found the time in which decomposition would take place considerably lessened.

While passing through this period of trial, experiment, and disappointment—speaking with reference to the various drugs I had been substituting for iodoform—a lady came to me one day with a history of dysmenorrhœa, from which she had suffered since girlhood. She had now been married several years without issue, and the pain during menstruation was steadily increasing. I found a long, narrow, and bent cervix, with erosions surrounding the os uteri, and a catarrhal exudate oozing therefrom.

This appeared to me a good case for rapid dilatation, and I so stated to the patient, giving my reasons for the opinion. She was a woman of culture and intelligence, and readily assented to the proposed future operation, I agreeing that it should be done after the next menstruation. Meanwhile, I proposed to cure the erosions and vaginal irritation that the acrid discharges were causing. Having some boric acid at hand that I had obtained for another purpose, it occurred to me to dust the os and upper vagina well with it, and to pack some dry cotton around the cervix to retain the boric acid in contact with the eroded surfaces, and particularly to keep the vaginal walls asunder.

Three days afterward I removed the packing, when, to my delight, the erosions were found changed to a more natural color, while the cotton was as sweet and inodorous as the day it was placed. This treatment was repeated at regular intervals, though more efficiently than at first, until the erosions were cured; but, alas! the

menses did not appear at the next expected period. The woman proved to be pregnant, and I was thus deprived of the opportunity of making a lucrative, and I trust successful, operation for the cure of her dysmenorrhœa and sterility. However, nature has done her work well, the dysmenorrhœa is cured, a young family is growing up with rapid increase, and I have no right to complain.

While treating this patient I had other opportunities of using this medicine daily, and I have continued it, for one reason and another, ever since.

The lessons this case taught me were:

1. That boric acid was an antiseptic of no mean value for intra-vaginal uses.

2. That it was chemically adapted to neutralize the acidity of the uterine and vaginal discharges, and thus contribute to the cure of sterility due to such causes. I have since had opportunities to verify this observation.

In the treatment of uterine and ovarian displacements, as I have before remarked, and in dealing with pelvic inflammations or their residues, it has been my custom for some years, in suitable cases, to employ vaginal tamponnement, either as a preparatory measure to other and more radical management, or as a curative agent, as the case might indicate or demand. I have described my method of packing the vagina for such purposes in considerable detail, not only in papers read in this Section but before other societies as well, and I only refer to it here and again in order to elucidate one or two points relating to it, for this paper may be regarded as in a measure supplementary to the others.

When I first began the systematic employment of vaginal tamponnement for the various conditions to which it is adapted, it was not expedient for the patients to retain the packing longer than twenty-four to thirty-six hours. This was partly because the work was done with less mechanical perfection, and hence the tampon would sag or become partially dislodged; but more especially because the secretions and exudates, natural and unnatural, would decompose and give off putrescent odors if left much longer.

Now, after twelve years or more, there has been much improvement in this simple but important mode of treatment. Then glycerine, carbolic acid, iodine, chloral, and perhaps a few other agents were employed to render the packing aseptic, and to promote shrinkage, absorption and osmosis. When iodoform came into vogue for this work it served a much better purpose, for it prevented decomposition for a longer time, was less irritating to the mucous membrane and, besides, possessed some inherent advantages as a curative agent.

But it is not my purpose now to chronicle the evolution of vaginal tamponnement for pelvic disease, from the primitive cotton-glycerine ball

of the earlier days, to the multiple wool tampon of the present. My object is more especially to invite attention to the fact that boric acid is a valuable drug to use in connection with this sort of treatment; and that, whereas under the old plan the tampon could not be permitted to remain longer than two or three days at the utmost, now I have no difficulty in packing the vagina so it will stay for a week, and that without emitting the slightest putrescent odor upon removal. This is of great moment, especially to patients who must needs come from a distance, and to those again who cannot afford more frequent visits to their doctor. Furthermore, I believe it better in many cases that this treatment be not repeated oftener than once a week. It is less disturbing to many women, psychically speaking, to have infrequent manipulations of the genital tract, no matter how delicately done; and, again, it is even better in many other cases not to disturb a well placed and efficient packing too often. We insure good pelvic rest, the elastic pressure is well maintained, the tampon keeps sweet. These, and many other reasons that I need not take time now to mention, all conspire to make it expedient—nay, even wise—to repeat the treatment as infrequently as possible or consistent with the welfare of the woman. Not all patients can wear the packing equally long; indeed, some should not be allowed to go a full week before its renewal, while others may carry it a little longer; but a week may be given as a fair average.

The method I adopt may be briefly and concisely described as follows:

First. Place the patient on her back and administer a copious hot vaginal lavement.

Second. Direct her to assume the knee-chest posture, introduce a Sims speculum or other retractor, wipe the vagina dry with absorbent cotton, dust the whole surface well with boric acid by means of a powder blower.

Third. Place two or three pledgets of cotton around the cervix, then turn into the vagina such a quantity of boric acid as may be desired—say a tablespoonful—and finally pack it neatly and quickly, even firmly, with wool pledgets, distributing the pressure where most needed.

At the end of a week—sometimes more, sometimes less—this packing is removed by the threads attached to each pledget, when the operation may be repeated.

This tamponnement of the vagina should always be preceded by the hot donche to insure a foundation of cleanliness, for which latter it is quite as important as it is for the effect it has on the circulation of the pelvic vessels.

The knee-chest posture affords the best opportunity, as a rule, to bring the boric acid in contact with every nook and cranny of the vagina, and enables the operator to pack the cavity snugly with less discomfort to the patient; yet, in some

cases where this posture is inexpedient, the Sims position may be substituted.

The method of doing the packing—its technique—is of considerable importance; for, if it be carelessly or indifferently done, its potency is greatly diminished. A little practice will readily suggest to the operator the proper course to pursue as to the amount of pressure, quantity of boric acid, and other details of the treatment. The principal feature to be borne in mind is that the tampon must not be uncomfortable by reason of its size, while at the same time it must be sufficiently ample in volume to be retained well in place.

Another way in which I have used boric acid with satisfaction must not be forgotten. After plastic operations in the genital tract I pour a quantity of it into the vagina, and then carry a rope of boric cotton up to the os uteri, allowing it to hang out over the perineum 2 or 3 inches. This may remain three or four days, and will protect the parts in various ways. The line of sutures—cervical, intravaginal or perineal—will be guarded antiseptically with a suitable dressing, that I cannot but regard as beneficial in promoting immediate union. I formerly used iodoform gauze in a similar way, but I like this plan much better.

There are many other gynecic uses of this drug that could be referred to, but I fear that I have already gone beyond the limits of a "Note."

The points upon which I wish to place emphasis are:

1. That boric acid is suited to many gynecic uses where antiseptics are required.

2. That it can claim superiority for vaginal tamponnement by reason of (a) odorless, (b) colorless, (c) non-irritant, chemical properties; these admitting of its frequent, liberal, and prolonged employment where this method of treatment is indicated.

3. That it is a remedy of value in sterility due to acrid secretions that destroy the fecundating power of the spermatozoa.

4. That it is one of the best powders to render operation wounds in the genital tract aseptic.

If I have given to even one person in this assemblage a single hint that may hereafter prove an aid to him, the object of this note will be served.

284 Franklin St.

## AN INTRODUCTION TO THE STUDY OF PNEUMONIC FEVER.

BY EDWARD F. WELLS, M.D.

EIGHTH PAPER.

CAUSATION: PREDISPOSING INFLUENCES.

There is much which we know of the causation of pneumonic fever; but there is vastly more of which we are, as yet ignorant. With the

lapse of time and the progress of knowledge we may confidently expect that the veil will be lifted and the Egyptian darkness dispelled. In no corner of the etiological field is there so much room for doubt and error as in the study of the predisposing<sup>1</sup> causes of diseases, and this is especially true of pneumonic fever.

This malady has been so often observed to occur during, or to follow upon some peculiar state of the general system, an injury or a disease, with such regularity and frequency as to lead to the inference that they exercise a predisposing influence over the production of the pneumonic fever. The explanation of the fact, however, is often, nay generally, not at hand. Yet even under these circumstances we should never lose sight of the fact that "every occurrence in nature is the result of some previous occurrence which we have agreed to call its cause, and which, in turn determines some other, which we consider its effect. Nothing is accomplished at any time by a sudden act of transition,"<sup>2</sup> or by chance.

A vigorous and robust constitution, joined, as it usually is, with active habits and a sanguine temperament, is thought by many<sup>3</sup> to predispose to the disease, whilst others<sup>4</sup> hold opposite views. It is probable, however, that one of the principal reasons why the strong and healthy are so frequently attacked is that they are usually more exposed to the deleterious influence of cold and wet, overexertion and worry and other predisposing causes of the disease.<sup>5</sup>

Of 171 cases analyzed by Chomel, 87 were strong, 36 average and 13 weak. Of Bouillaud's 26 cases, 20 were strong and 6 weak. Of Bennett's 118 cases, 49 were in bad health when attacked. Of 750 cases tabulated by Patton only 18 per cent. were previously healthy. Of my 498 cases 134 were strong, 267 average and 97 weak.

Some persons, without any obvious reason, are peculiarly predisposed to, or exempt from, attacks of pneumonic fever, and this proclivity or immunity may extend to entire families, tribes or races.<sup>6</sup> In some instances immunity, for example, is clearly due to exceptionally favorable hygienic,<sup>7</sup> climatic or other external influences; or to certain states of the system, such as pregnancy<sup>8</sup> or

chlorosis,<sup>9</sup> in females, or advanced emphysema,<sup>10</sup> etc.

The inhalation of various noxious gases, fluids and solids may act as a predisposing cause of the disease. The lungs act as a filter and retain much of the irritating substances which find access to them,<sup>11</sup> and these may light up a local inflammatory process<sup>12</sup> which serves as a nidus for the development of the pneumonic poison, or render the system less able to resist its onslaughts.

Of such substances we may mention gasses arising from the combustion of anthracite and other coal,<sup>13</sup> natural gas,<sup>14</sup> sewer-gas,<sup>15</sup> smoke, steam and heat, the fumes of acids<sup>16</sup> and bromine,<sup>17</sup> vapor of chloroform and other anæsthetics,<sup>18</sup> cinders, pollen, dust from hemp works, flouring and planing mills, cotton gins and cotton mills,<sup>19</sup> seed and grain threshing machines,<sup>20</sup> needle, edged-tool and gun-barrel grinding, button and nail<sup>21</sup> making, mining,<sup>22</sup> quarrying<sup>23</sup> and various other foreign matters.<sup>24</sup>

<sup>10</sup> Gerster, *N. Y. Med. Rec.*, April 23, 1887, p. 453; Wyeth, *Ibid.*, p. 474; et al. Gerster has given a series of very interesting cases in which pneumonic fever followed the employment of anæsthetics.

<sup>11</sup> A female, aged 43, submitted to lumbar colotomy, under ether. On the following morning a severe chill ensued, followed by the ordinary symptoms of pneumonic fever and death on the fourth day. The entire right lung was solidified.

<sup>12</sup> A man, aged 60, was castrated, under ether, and was attacked with pneumonic fever two days later. The temperature rose to 106° F. and death speedily ensued.

<sup>13</sup> A man, aged 61, underwent inguinal colotomy, under ether, and on the next day was attacked by pneumonic fever, locally affecting the entire right lung.

<sup>14</sup> A man, aged 25, who had recently had pneumonic fever, took ether for the extirpation of the inguinal glands. The affection re-appeared in the same lung and proved fatal.

<sup>15</sup> A woman, aged 50, was operated upon, under ether, for ruptured perineum. Pneumonic fever developed immediately and terminated fatally.

<sup>16</sup> A boy, aged 16, had the inguinal glands removed, under ether. Severe pneumonic fever ensued. Recovery.

<sup>17</sup> It may be that the pneumonic inflammation is due less to the effects of the anæsthetic than to the exposure and chilling of the patient by the extensive over-covering and wetting of parts usually clothed. See Wier, *N. Y. Med. Rec.*, April 23, 1887, p. 473; Abbe, *Ibid.*, p. 474. For further information as to the effects of anæsthetics on the lungs see *Brit Med. Jour.*, Dec. 15, 1889.

<sup>18</sup> Mocr, *Rpt. Health Officer*, Oldham, 1886.

<sup>19</sup> I have met with an interesting series of cases of pneumonic fever following exposure to the dust of clover-hulling machines. Of these the following are examples: A farmer, aged 42, engaged in threshing clover, was attacked with pneumonic fever, locally affecting the entire left lung. Three days later the base of the right lung also became involved. Recovery was long delayed by a small abscess in the right lung, which only began to improve after the expectoration of a thick mass of pus in which were imbedded some small, dark objects, supposed to be pieces of clover-hull. A young man, engaged in like occupation, developed pneumonic fever, the local processes pursuing a lingering course; improvement following closely upon the expectoration of a small piece of clover-hull. Another gentleman, of middle age, likewise engaged, was attacked with pneumonic fever, with diffused local consolidations, which also pursued a lingering course.

<sup>8</sup> Juergensen, *Ziemssen's Handb.*, Bd. v, S. 28; Pause, *Lungenentzündung*, 1861, S. 64.

It has been doubted, and even denied, that suspended solid matters could reach the alveoli, but the observations of many writers disprove the assertion.<sup>25</sup>

A curious case of pneumonic fever came under my notice several years ago: A male epileptic imbecile, æt. 22, shortly after eating, was taken with a fit, falling to the ground with his face in a shallow depression. Whilst in this position he vomited freely and some of the ejecta found their way into the lungs. The inflammation was confined to the apex of the left lung, pursued an ordinary course and terminated in recovery.

Filling of the bronchi with water, as in submersion, is not infrequently followed by pneumonic fever.

The foreign matters may be of a septic nature and cause pulmonary inflammation of a peculiar character, besides infecting the system generally. This is what occurs when the poisonous dust arising from fleeces of wool infected with anthrax is inhaled.<sup>26</sup>

The foreign material may be a body of considerable size, and may remain for a long time in the lungs without causing disease, but so long as it or its effects remain it is an element of danger.

Hargrove<sup>27</sup> relates the following case: In the autumn of 1866 a cockle-burr was lodged in the right bronchus of a healthy woman of 18. After subsidence of the first violent symptoms no serious inconvenience was encountered until February, 1869, when acute pneumonic inflammation developed in the right lung. A second attack ensued in June and the final one in July. At the autopsy both lungs were found inflamed, with an abscess on the surface of the right one. The burr was in a perfect state of preservation.<sup>28</sup>

The secretions of the respiratory tract, especially bronchial, when aspirated into the finer tubes and alveoli act as foreign bodies, and, when not promptly expelled, may pave the way for pneumonic inflammation. Collapse of lobules may

produce the same effects. The solid and semi-solid secretions sometimes formed in the nares, tonsils, pharynx, larynx, etc., may also cause like results should they become dislodged and find their way into the peripheral areas of the respiratory tract.

Blood, pus and acrid, putrid or other secretions from wounds or diseases of the respiratory tract may pass into the finer bronchial tubes and be followed by pneumonic fever.

This may occur in cancrum oris,<sup>29</sup> scurvy and other ulcerative diseases of the mouth,<sup>30</sup> cancer of the tongue, pharynx or larynx and the operations for its relief,<sup>31</sup> diphtheria, tracheotomy and laryngeal intubation,<sup>32</sup> calculus of the bronchi,<sup>33</sup> chronic bronchitis,<sup>34</sup> hæmoptysis,<sup>35</sup> etc.

Disease and injury of the central nervous system are very frequently followed by pneumonic fever.

Calmiel,<sup>36</sup> in an analysis of 188 cases of organic disease of the brain found acute inflammation of the lungs present in nearly one-third of them.

A girl, æt. 5, received an injury of the head by being run over by a carriage. Two or three days afterwards feverish symptoms set in, with stupor, stertorous breathing, tremulous pulse, involuntary discharge of feces, convulsions and, finally, death. At the autopsy no gross lesion was found within the cranium, but the right lung was found violently inflamed and consolidated.<sup>37</sup>

A man, æt. 26, received a pistol-shot wound of the head, from which he had partially recovered, when, after exertion, pneumonic fever developed and terminated fatally in ten days. At the autopsy the ball was found, partially encysted and partially imbedded in the jugular fossa. The pulmonary vessels were everywhere dilated, with

a reticulated exudation in the alveoli and thickening of the pleura.<sup>38</sup>

That pneumonic fever often prevails in connection with cerebro-spinal fever has long been a matter of common observation.<sup>39</sup>

In these cases the pneumonic inflammation is due either to pulmonary extravasation,<sup>40</sup> local vasomotor paralysis, paralysis of the vagus<sup>41</sup> or paresis of the respiratory muscles.<sup>42</sup> Paralysis of the soft palate and pharynx may be followed by the disease.<sup>43</sup>

When the vagus is implicated irritative matters pass readily into the lungs, from whence they, together with the mucus secretions, cannot be again dislodged. Inflammation is the result.

A boy, æt. 12, suffered a mild attack of diphtheria and apparently recovered in due season. After the lapse of three weeks there supervened a gradually increasing paralysis of the palate to such an extent that swallowing liquids was a very difficult procedure—being invariably accompanied by regurgitation through the nares, and often by coughing and choking. Ten days later pneumonic fever was developed, ending in recovery. The faucial paralysis gradually improved, but was still present to a slight extent eight years afterwards.

It has been believed that insanity predisposes to pneumonic fever,<sup>44</sup> but after an attentive study of a great number of asylum reports I cannot confirm the supposition. The influences of the passions, hope, fear, anger etc., in this direction are not fully known.<sup>45</sup>

Otitis media is not infrequently complicated by pneumonic fever.<sup>46</sup>

In 1880, I saw in consultation a child, æt. 3, that had been ill for three weeks with otitis media purulenta with perforation of the drum membrane. Two days previously the discharge had ceased, followed by fever, delirium, incessant vomiting, cough and the evidences of inflammation at the bases of both lungs. Icterus and effusion into the left pleural sac ensued and he died a week later.

A female child, 1 year old, was restless for a day, awoke from sleep with fever, retraction of the head, a nasal discharge, a stifled cough and a piercing cry, followed by moaning. Four days later there were presented the evidences of pneumonic consolidation at the base of both lungs and distention of the tympanic cavity. The drum membrane was punctured and exit given to a small amount of purulency. The discharge became free after a few hours, and the pulmonary symptoms rapidly subsided.

A young lady, æt. 22, experienced for a few days the ordinary symptoms of a "cold in the head," notwithstanding which she exposed herself for several hours to intense cold. This was followed by intense pain in both ears, fever, epistaxis, delirium, dry tongue, sordes, total deafness, cough and rusty expectoration. Examination on the fifth day revealed hepatization of the base of the left lung. The right ear was discharging and the left drum membrane was punctured. Recovery, including hearing ensued.<sup>47</sup>

Injuries of the chest may be followed by pneumonic fever,<sup>48</sup> although it is not a necessary consequence.<sup>49</sup>

A boy, æt. 15, engaged in a scuffle, was sprung upon by his antagonist, who knocked him down and knelt upon his breast. Pain at the injured spot was at once complained of, although there was no outward injury to be seen. Illness came on, with fever and the symptoms of pulmonary inflammation. Death occurred after ten days and the autopsy revealed consolidation of the lung beneath the seat of injury.<sup>50</sup>

A simple, uncomplicated, fracture of the ribs, although seldom followed by pneumonic inflammation in the young, may be so in the aged subject of chronic bronchitis. Under these circumstances a fracture of the first rib or clavicle is of

<sup>38</sup> Fisher, N. Y. Med. Jour., Aug. 25, 1883, p. 222.

Rec., June 15, 1872; Carpenter, N. Y. Med. Rec., July 16, 1887, p. 85, et al.; Wood—N. Y. Med. Rec., May 14, 1887, p. 557; Robinson, Ibid., p. 558, and others—have not been able to observe any relation between the two diseases.

<sup>40</sup> Brown-Sequard, in experimenting on animals, found that if an injury of the head was survived for a time that pneumonic inflammation frequently ensued. After such injuries emphysema and numerous minute extravasations were found in the lung on the side opposite the cerebral injury. See London Lancet, Jan. 7, 1871.

These observations are confirmed by those of Fleischmann—Centralbl. f. d. Med. Wissensch., 1871, Nr. 28—on men, and a case reported in the U. S. Marine-Hosp. Rpts., 1883, p. 262.

<sup>49</sup> Fraser, Wounds of the Chest, London, 1839; Flint, N. Y. Med. Rec., July 14, 1877.

<sup>50</sup> Morgagni, De Sed et Cur. Morb., Lib. ii, Ep. xx, S. 28.

serious import, inasmuch as they are the starting point—the fulcrum, as it were—of the system of respiratory muscles, and it is upon the integrity of this base of support that their proper function depends.<sup>51</sup> In these cases the respiratory movements and cough are restrained and impeded by pain, and the bronchial secretions flow into the alveoli, causing irritation and inflammation. Not only do such results occur from the injury alone, but in some undoubted instances the surgeon has unconsciously aided in bringing it about by applying bandages so tightly as to still further impede the action of the respiratory muscles.

Hernia of the lung and paracentesis of the thorax<sup>52</sup> may be followed by pneumonic fever.

Pneumonic fever has frequently followed other injuries<sup>53</sup> and operations, *e. g.*, concussion of the lungs,<sup>54</sup> caries of the spine,<sup>55</sup> resection of ribs,<sup>56</sup> resection of joints,<sup>57</sup> resection of the pylorus,<sup>58</sup> injuries to nerves,<sup>59</sup> burns and scalds,<sup>60</sup> the bites of rabid and other animals,<sup>61</sup> the bites of venomous snakes,<sup>62</sup> pulmonary apoplexy,<sup>63</sup> etc.

It has been supposed,<sup>64</sup> but most probably erroneously,<sup>65</sup> that overexertion of the lungs, as in public speaking, singing, playing wind instruments, etc., predisposed to the disease. Excessive bodily exertion, especially when accompanied by anxiety is a factor in its causation.<sup>66</sup>

Pneumonic fever may also follow or accompany various diseases of near or distant organs or structures, *e. g.*, pericarditis,<sup>67</sup> inflammation of the respiratory tract above the air-cells,<sup>68</sup> inflammation of the bronchial glands,<sup>69</sup> abscesses of the thoracic walls,<sup>70</sup> spleen,<sup>71</sup> liver,<sup>72</sup> abdomen,<sup>73</sup> pelvis,<sup>74</sup>

spine,<sup>75</sup> neck,<sup>76</sup> etc., thoracic aneurism,<sup>77</sup> stricture of the œsophagus,<sup>78</sup> pleurisy,<sup>79</sup> chronic heart disease,<sup>80</sup> obstruction of the bowels,<sup>81</sup> acute myositis,<sup>82</sup> ulcerative endocarditis,<sup>83</sup> pyæmia<sup>84</sup> and other morbid states of the blood,<sup>85</sup> chronic cancerous disease,<sup>86</sup> narcotic poisoning,<sup>87</sup> acute and chronic alcoholism,<sup>88</sup> albuminuria and other renal diseases,<sup>89</sup> including diabetes,<sup>90</sup> the acute exanthemata,<sup>91</sup> ery-

The intimate relations existing between the lung and its serous envelope sufficiently explains why it is that the one is scarcely ever inflamed without involvement of the other. This fact has been recognized by every observer from the most ancient to the present time.

sipelas<sup>92</sup> and chronic skin diseases,<sup>93</sup> cholera,<sup>94</sup> influenza,<sup>95</sup> glanders,<sup>96</sup> difficult dentition,<sup>97</sup> malarial intoxication<sup>98</sup> although some vehemently deny that it bears any causative relation to the disease in question;<sup>99</sup> typhus, typhoid<sup>100</sup> and other forms of continued fevers,<sup>101</sup> plague,<sup>102</sup> dysentery,<sup>103</sup> senile gangrene,<sup>104</sup> rachitis,<sup>105</sup> melanosis,<sup>106</sup> sweating feet,<sup>107</sup> vesicle calculus,<sup>108</sup> pulmonary phthisis,<sup>109</sup> gonor-

rhea and other venereal diseases,<sup>11</sup> rheumatism,<sup>111</sup> pertussis,<sup>112</sup> mumps,<sup>113</sup> etc.

Not only may various diseased states<sup>111</sup> be accompanied by pneumonic fever, but the malady may follow the cure of some others, *e. g.*, chronic ulcers,<sup>115</sup> chronic agues,<sup>116</sup> rectal sinuses<sup>117</sup> hæmorrhoids, etc.

A gentleman, æt. 50, for twenty years a martyr to bleeding piles, was operated upon by the injection of a glycerinated solution of carbolic acid. The operation was successful, but was soon followed by pneumonic fever, locally affecting the base of the right lung. Great relief followed the application of a blister to the affected side, a seaton to the inside of one thigh and of leeches around the anus. Recovery ensued.

(To be concluded.)

## MEDICAL PROGRESS.

ON DIABETES MELLITUS.—SEEGEN (*Zeitsch. für Klin. Med.*, XIII., p. 267) regards the mild form of diabetes—diabetes of the fleshy—as purely of a hepatic origin. The cells of the liver alone are affected; in consequence of an anatomical or chemical change as yet unknown they have lost their glycogenic power. A large portion of the sugar introduced by the food is thus no longer utilized but carried off in the urine. In this form of diabetes diet has great therapeutic effect. The severe form of diabetes, diabetes of the lean, is due on the other hand to a change of all the cells of the organism which have lost their power of utilizing the sugar furnished by the blood. Diet in these cases will merely have a pallia-

tive effect. In patients with diabetes, besides tuberculosis, a special fibrous pneumonia (already described by Riegel) is often observed. Fink reports a new case (*Münch. Med. Woch.*, No. 37, 1887) in a man 32 years old, who had been afflicted for three years with sugar-diabetes, and in whom three months before death an indurative sclerosis of the right lung, with dilatation and purulent secretion of the bronchii, had been diagnosed. Tubercle-bacilli were never found in the sputa. The autopsy confirmed the diagnosis, but did not show in the sclerosed tissue any bacilli nor tubercular nodules.—*Revue des Sciences Médicales*, No. 66, 1889.

GONOCOCCI IN A DISCHARGE FROM THE URETHRA WITHOUT SEXUAL INTERCOURSE.—PROF. STRAUS reports (*Arch. de médecine expérimentale*, No. 3, 1889) the case of a youth 16 years old who had practiced masturbation for four years and who, a week before applying to the physician, M. Mauriac, had practiced the vice more actively than usual. Two days afterwards pains while urinating, and shortly after well-defined symptoms of gonorrhœa, were noticed. Patient absolutely denied that he had had any intercourse with women, and M. Mauriac was inclined to give credence to his assurance. The discharge contained the typical gonococci of Neisser, and it was impossible to distinguish them from those found in the discharge of a patient afflicted with common gonorrhœa.

If the assertion of the young man was truthful a great deal of importance attaches to this case, as it goes to show that the gonococcus of Neisser may exist as an inoffensive lodger and simple saprophyte in the healthy urethra, and that under the influence of harmful irritation it may invade the epithelium and cause the characteristic catarrh.—*Revue Médicale de l'Est*, No. 9, 1889.

ON THE DEVELOPMENT OF MALARIA PARASITES IN FEBRIS TERTIANA.—The causal relations between the peculiar plasmodii occurring in malaria inside of the red blood-corpuscles and the origin of the disease are almost universally recognized by the investigators of the present time. Most of them, as for instance Laveran, Marchiafava and Celli, Councilman, etc., do not hesitate to ascribe diagnostic significance to the proof of the existence of these formations in the individual case. Golgi goes a step farther. Already in earlier works he had attempted to show that the malaria parasites in the blood of patients go through a regular course of development, the various stages of which are closely related with the recurring fever attacks.

Inside of the red blood-cells pigmented formations are said to grow from the uncolored amœboid, incipient forms of the plasmodii which constantly grow in size by absorbing the substance of the

blood-corpuscles, and finally begins to divide, a process which coincides precisely with the beginning of the fever, or precedes it directly. The result of the division is the birth of new generations of microorganisms which gain an entrance into other red blood-corpuscles and there continue the process, *i. e.*, cause new attacks of fever, whilst the remaining melanin which originated at the destruction of the hæmoglobin and had been freed by the process of division, is absorbed through phagocytosis by the leucocytes in the circulating blood or inside the organs.

It is claimed that the presence of the perfectly developed bodies and of the immature ones indicates the impending outbreak of an attack, that by accurate observation of the various stages of development of the parasite the beginning of an attack can be foretold one or two days previously, and finally that it can be shown whether the conditions exist for a single attack (*febris quartana*), or for two attacks (double *febris quartana*), or for three attacks (trifold *febris quartana*, *i. e.*, forms of the *febris quotidiana*), according to whether one generation or several successive generations of the plasmodii appear. All these facts had been established only for the *febris quartana* with its varieties just mentioned, whilst according to Golgi's opinion the parasite causing the malarial infection in *febris tertiana* must have a different course of development.

To prove in detail this latter statement is the purpose of an article by Golgi in *Fortsch. d. Med.*, 1889, No. 3, according to which the essential points of difference between the tertian and quartan species of the plasmodii are as follows: The amœboid forms, not pigmented, which represent the incipient stage in the development of the micro-organism and always lie inside of the red blood-corpuscles, show much more lively movements in *febris tertiana* than in *quartana*; they are, furthermore, capable of destroying and absorbing the hæmoglobin of the blood-corpuscles with especial rapidity, so that in *febris tertiana* the infected blood-cells appear as colorless formations in the first hours of the day between the two attacks, whilst in *febris quartana* their characteristic yellowish-green coloring is preserved to the end. The protoplasm of the *tertiana* plasmodii has a more delicate look than that of the *quartana*; the former deposit the pigment within themselves in a much finer, small granular mass than the latter; but above all the process of division occurs in the two in an essentially different manner. In the *tertiana* each plasmodium is divided into 15-20 new elements, in the *quartana* into 6-12, which are correspondingly larger than the former. In the interior of the globules thus formed, *i. e.*, of the parasites, in the *quartana* a glittering little body is seen, a sort of nucleus, which is missing in the *tertiana*, etc.

These points of difference enable us, by means

of a simple examination of the blood to recognize *febris tertiana* and to make its differential diagnosis from other varieties of *febris intermittens*. The relations between the various stages of development of plasmodii and the stages of the disease are the same in *febris tertiana* as in *febris quartana*."

In view of the importance which these observations of Golgi, if proven correct, have for our knowledge of the character of malaria, it is desirable that at least the principal types of the most important and most characteristic forms here described be made more generally known by photography.—*Centralblatt für Bakteriologie und Parasitenkunde*, No. 18, 1889.

ON CARDIAC CONTRACTIONS.—VON ZIEMSEN studied, by the aid of tracings, the successive phases of the cardiac revolution. Between the moment of complete relaxation and of the first valvular tone, the contraction is represented by a rather quickly ascending curve followed by a line still ascending approaching the straight, but a little longer and approaching more the horizontal. Between the first and second murmurs the cardiac sketch presents an ascending, almost vertical line, terminating in a rounded bend the summit of which corresponds to the most active phase of contraction. Then the curve descends again about as rapidly to a level a little above that which corresponds to the beginning of this second phase. The curve ascends again twice, but feebly. Of these two summits, which are much lower than the first and correspond to a normal diastole, the last one is the lower and coincides with the second murmur. Thereupon the curve descends again a little less abruptly to the lower level of the trace, the whole of which thus represents the totality of a cardiac revolution. The experiments made with alcohol and digitalis prove that, with the latter, the duration of the phase intervening between complete relaxation and the first valvular murmur is alone influenced; it is shortened with the former and prolonged with the latter. This duration was from 0.18 to 0.46, the normal duration being 0.25. In the same experiments the remainder of the trace and the respective duration of the other phases did not differ from the normal.—*La Semaine Médicale*, No. 17, 1889.

EXPERIMENTAL PRODUCTION OF RENAL CALCULI.—EBSTEIN, of Göttingen, has made, together with NICOLAÏER, experiments on dogs and rabbits, and succeeded in producing in these animals, by introducing oxamide into their food, renal concretions, the most voluminous of which was found in the pelvis of the kidney, whilst the gravel or grit of the oxamide was found in all parts of the urinary apparatus. Although the oxamide injected was white, the renal concretions

were of a greyish yellow. The largest of them showed on their surface wrinkles and roughness. The calculi are quite hard and, on polishing them, one finds upon the surface thus obtained circles or parts of concentric circles, between which concentric layers can be seen presenting radiating striations. These concretions are composed of oxamide and an organic skeleton showing the reaction of an albuminoid substance. By treating these calculi with hot water of 80° to 90°, the oxamide dissolves and leaves a bare organic skeleton, the sections of which show an aspect similar to that of the ground surfaces; only the suppression of the radiations reveals the relation existing between these starred fibres and the presence of oxamide.—*La Semaine Médicale*, No. 17, 1889.

ON THE UTILITY OF SPECIFIC GRAVITY AND THE QUANTITY OF ALBUMEN IN PATHOLOGICAL TRANSUDATES AND EXUDATES FOR THEIR CLINICAL DETERMINATION.—DR. E. NEUENKIRCHER, of Riga, gives as the result of a series of calculations the following: Pleural and peritoneal transudates and exudates are characterized according to their genesis by various specific gravities. The average figures of the specific gravity are lowest in pleural and peritoneal transudates caused by morbus Brightii; a higher specific gravity is shown by peritoneal liquids in cirrhosis hepatis, then follow the pleural and peritoneal transudates in general venous stasis, the ascites in carcinoma hepatis, the pleural and peritoneal exudates in carcinoma peritonei and pleuræ, the exudates in idiopathic and tubercular pleuritis, and the highest specific gravity is shown by exudates in purulent pleuritis. For prognostic purposes of an individual case the changes of the specific weight in repeated punctures can be utilized only with great care. As a general rule, the falling off of the specific gravity in such cases denotes a deterioration of the general condition of the patient and presents an evil prognostic symptom.—*St. Petersburger Medicinische Wochenschrift*, No. 13, 1889.

A CASE OF ALOPECIA AREATA AFTER OPERATING ON THE NECK.—PONTOPPIDAN has made an observation in a man (*Monatssch. f. prakt. Dermat.*, viii, 2, S. 51), which is closely related to the examinations made by Joseph (Berlin) of the second cervical nerve of the cat. A girl 10 years of age was operated upon for a glandular swelling the size of a pigeon's-egg in the left carotid region. That portion of the glandular growth imbedded deeply was adherent to the external jugular vein, and during the loosening of it a rather violent bleeding from a rent in the vein occurred. The hæmorrhage was stopped by tampon with iodoform gauze saturated with sublimate solution and compression with bandage. After removing the latter on the twenty-first day two symmetrically bald spots, circular, about of the size of a dollar,

were discovered on the back of the neck. Micro-organisms could not be found. The spots rapidly grew in size; new ones appeared toward the middle of the head and behind the ears, and ran together. After about seven weeks the height of development was reached, and then the extent of symmetrical baldness corresponded to the area supplied by the N. occipit. maj. and minor and the rear branch of the N. auricularis magnus. The skin was smooth and normal, sensibility not disturbed. Five weeks later the entire portion was covered quite thickly and uniformly with new lanugo-like hairs.

Here is an illustration of an alopecia areata occurring after a lesion of the upper cervical nerves. The most probable explanation is that a neuritis was caused by the tampon and the compression of the origins of the cervical nerves. The symmetrical spreading of the baldness toward the side not operated upon is remarkable. Pontoppidan considers an invasion of the corresponding nerve area of the other side, perhaps by a neuritis centripetally transmitted, as possible.—*Centralblatt für Physiologie*, No. 2, 1889.

ON THE TREATMENT OF THE PAINFUL SYMPTOMS OF PHTHISIS OF THE LARYNX.—It is especially in cases where the lesions predominate on the level of the upper orifice of the larynx that intense pain is experienced at every movement of deglutition, preventing the most indispensable functions for strengthening the organism—those of alimentation. Previous to the discovery of cocaine opiates constituted the most efficacious means for relieving the sufferings of the patient. The muriate of morphine may be mixed either with an inert powder (powdered sugar), or with an antiseptic or modifying powder, in the following proportions:

Powdered sugar . . . . . 10 gr.  
Powder of muriate of morphia 1 gr. or 0.50 gr.

OR

Iodoform (pulverized) . . . . . 10 gr.  
Powder of muriate of morphia 1 gr. or 0.50 gr.

A pinch of one of these powders is put into an insufflator bent for the purpose, and, with the aid of a mirror, applied to the ulcerated parts. This little operation may be done preferably in the evening, so as to serve the two-fold purpose of rendering alimentation and sleep possible. As stated above, the discovery of cocaine has furnished us with a means of much greater efficacy for local anesthesia. This drug appears to best advantage in the treatment of phthisis of the larynx. The muriate of cocaine can be applied by insufflation the same as morphia, in one of the following proportions:

Powdered sugar or iodoform . . . . . 10 gr.  
Muriate of morphia . . . . . 1 gr. or 0.50 gr.  
Muriate of cocaine . . . . . 1 gr. or 0.50 gr.

But its effect is greater in solution, in water mixed

with glycerine, so as to enable the liquid to better adhere to the tissues.

Water . . . . . 5 gr.  
Glycerine . . . . . 2 gr.  
Muriate of cocaine . . . . . 1 gr. or 0.50 gr.

By means of pincers or bent wadding-carriers, and with the aid of a mirror, the epiglottic and aryteno-epiglottic region is washed with this solution and thus within a few minutes an anesthesia is obtained sufficient to allow the patient to take his meal without great suffering.—*Journal de Médecine de Paris*, Vol. xvi, No. 16, 1889.

A CASE OF TENIA IN A BABY 10 WEEKS OLD.—A baby 10 weeks old was brought to DR. MENSINGA, of Flensburg, the father of the child having previously shown to him a sort of worm said to have come from the anus of the patient. With the child the parents brought, in alcohol, about twenty links of a tenia. The baby had just had a stool. The feces in the diapers were quite compact and full of moving proglottides which, changing peristaltically their forms, completely pervaded the feces.

It was discovered that the man had killed a pig when the child was two weeks old and, on finding that it was measly, sold it in the city. Peculiar circumstances must have combined to introduce the germ of the tenia into the baby. Nourishment—milk not boiled—being given to the latter with the bottle, the dishes had probably been used for the milk as well as for the pig-killing, and not being cleansed thoroughly, having thus carried the affection to the child.—*Internationale Klinische Rundschau*, No. 17, 1889.

CALCULATION OF SMALL QUANTITIES OF SUGAR IN THE URINE.—To ascertain the quantity of sugar in the urine when less than 0.2 per cent. is difficult but useful. Some individuals have but a small quantity of sugar in the urine when they have taken a great deal of hydrocarbons, and in the lighter cases of diabetes it is this kind of food which causes glycosuria.

POLLATSCHKE (*Deutsche Med. Wochenschrift*, No. 18, p. 354, 1888) advises to treat the urine with carbon before reducing the copper. A small quantity of charcoal is put into the test-tube, the mass is stirred up and filtered; the urine is then clear and freed from substances which might render the analysis uncertain. In another test-tube equal proportions of solution of sulphate of copper, Rochelle salts and soda are mixed and heated. If the mixture remains clear the filtered urine is added and heated again; the precipitate is yellow, rarely red. For control subnitrate of bismuth, hydrochlorate of phenyl-hydracine, which Jaksch recommends, is used.—*Revue des Sciences Médicales*, No. 66, 1889.

THE  
Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE.....\$5.00  
SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 7274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JULY 13, 1889.

THE ANNUAL MEETING AT NEWPORT.

The Fortieth Annual Meeting of the Association was in every respect a success. The Committee of Arrangements had so perfectly accomplished its work that ample provision was made, not only for the General Sessions, but for each of the Sections as well.

The Association was particularly fortunate in the selection of its officers. The programme for each Section gave evidence of thorough and judicious preliminary work.

The profession of the entire country was represented in the preparation and discussion of papers. Every hour assigned to Section-work was fully occupied, and in several instances two, and even three extra sessions were required to complete the programme.

Attractive as were the social features arranged for each day, still it was a noticeable fact that but few of the members could be diverted from the real purposes of their assemblage, and from first to last each Section was ably represented by a full corps of earnest workers.

Many papers of unusual value were presented, and their careful perusal, as they shall appear in THE JOURNAL, will reward the reading.

BEDSIDE HYGIENE IN TYPHOID FEVER.

The instructive Address on State Medicine given by DR. W. H. WELCH, of Baltimore, at the recent meeting of the Association, should emphasize anew in the mind of every general practitioner the oft taught, but oft neglected, lesson,

that the physician's duty in cases of infectious disease is but half fulfilled in his most solicitous care for the patient's individual welfare. To prevent the extension of the malady from the sick-room to the household—from the household to the community, is an even more important obligation.

Although the mystery of the *vera contagia* is still unsolved in a strictly scientific sense, enough is known of the ordinary conditions of their evolution and transmission in many instances to facilitate the application of what we may venture to call "clinical hygiene." Aside from all theoretical controversies concerning the part played by microorganisms—as causes, carriers, or merely ferments operative only in suitable media—we know that a morbid something is extruded from the sick; in the cases most commonly brought under our attention we know the channels of extrusion; and with this knowledge we can reasonably, if empirically, adopt appropriate preventive measures.

For example: In the specific diarrhœal disorders of which typhoid fever may be taken as a type, it is generally agreed that the infective *materies morbi* lies in the intestinal excreta, and that even in these, when freshly voided, we have an interval of comparative innocuousness during which precautions may be safely exercised. If action be promptly taken at this time, we may spare ourselves the perplexing consideration of the relative dangers of contamination of water, soil, air, or food; but if such action be tardy or unintelligent, the widespread resultant mischief may long baffle the wisest resources of public sanitation. Assuming Eberth's bacillus to be at least the specific ferment whereon depends the evolution of the virus of enteric fever, it seems proven that this microzyme can sustain itself, for some days, at all events, under a temperature exceeding 112° Fahr., or below the freezing point; that it sporulates in the range between 66° and 104°; that it multiplies even more vigorously in comparatively pure than in very impure water; that it finds a congenial habitat in damp soil, and yet resists desiccation for an undetermined period. It is destroyed by boiling, by even weak solutions of mercuric bichloride, by chloride of lime and some other chlorides, and its growth is retarded by acids. The safest disinfectant to be intrusted to unskilled hands is fresh chloride

of lime, or the official solution of chlorinated soda. For the excreta, the former of these may be used in saturated solution, or the latter undiluted, and they should be employed immediately; for textile fabrics which have been soiled by the discharges, and which it is undesirable to burn, boiling will be effective, but it should be done as soon as possible after the soiling. Disinfection by steam of bedding and other articles which cannot be thus treated is hardly practicable until, if ever, public provision shall be made for it. With proper care in nursing, however, such things may be easily protected from infection. Even during convalescence, vigilance with regard to the dejecta should not be relaxed, as in exceptional cases bacilli have been found in the stools a fortnight after the reduction of the temperature to the normal line.

The task of bedside sanitation thus outlined is neither a difficult nor an exacting one, and if the family physician bear it always in mind he will forestall the far less hopeful labor of the health officer.

#### AN INTERESTING CASE OF ASTHMA.

In the *Berl. Klin. Wochenschr.* of December 10, 1888, there was reported by PAWINSKI a case of asthma which presented a remarkable condition of auto-intoxication, apparently, as shown by the urine. Large amounts of acetone were discovered in this secretion upon the occurrence of each attack of asthma, while during the intervals it could be found only in traces. The patient, a young woman, was seized by the asthma after having been at a dance the previous night. When seen by Pawinski she presented the customary phenomena of such an attack, together with demonstrable enlargement of the heart. The case was under observation for some time and always presented acetonuria. It subsequently terminated fatally.

This case is of special interest for two reasons: 1. Because it indicates that acetone, which is known to be linked to an increased decomposition of the tissues, as in fever, carcinoma, diabetes, starvation and the like, may be produced by conditions in which so disastrous a breaking up of tissue is not apparent and might, therefore, be overlooked, and that the accumulation of this substance in large amounts acts as a profound poison to the central nervous system. 2. Because

systematic examinations of the urine, in cases of asthma, may lead to the detection of many conditions not now recognized as predisposing causes of asthma.

"A word to the wise is sufficient," and hence, if one will profit by the lesson taught by this case, he will not neglect the examination of the urine in each case of asthma whose etiology is at all obscure.

#### THE RENOVATION OF NAPLES.

At last wise counsels have gained the ear and the confidence of the Italian Government. The phrase "See Naples and die," had come to have a fearful and literal significance, and the Neapolitan fever was the dread of all foreign travelers. But the day of its renovation has come to the beautiful city of Naples.

What Italy does, it does thoroughly, and this is no ordinary movement which the Government is making. It means the demolition of seventeen thousand houses and of sixty-two churches in the very heart of the city. It means the expenditure of over forty millions of dollars in one stupendous sanitary work, the cost to be borne mainly by the Italian Government. But let the health and prosperity of Naples be once more assured and the returns, even for this large expenditure, will be tenfold. The impetus thus given to the subject of sanitary science is to be world-wide in its results. Other cities have like needs. Other governments should follow this example.

#### INDIVIDUAL EFFORT.

It would seem a small matter that during the ensuing year each member of the Association should secure for THE JOURNAL one additional subscriber. The doubling of the subscription list would warrant such an outlay for the improvement of THE JOURNAL as would well repay the effort. The Association would at once command a wider influence and the profession at large secure to themselves a benefit too valuable to be lost. Will those members of the Association who have its welfare and the best interests of the profession at heart give us a helping hand, while we labor earnestly to increase the value and usefulness of THE JOURNAL?

*Will each member secure one new subscriber?*

## EDITORIAL NOTES.

## HOME.

MCGILL UNIVERSITY.—Dr. George Ross has been appointed Professor of the Practice of Medicine, and Dr. Richard Z. McDonnell Professor of Clinical Medicine in the Medical Faculty of the University.

DR. WM. W. KEEN succeeds the late Dr. S. W. Gross as Professor of Surgery in Jefferson Medical College, Philadelphia.

DETROIT BOARD OF HEALTH.—At the annual meeting of the Board of Health of the city of Detroit Dr. Wm. Brodie was elected President. The members of the Board are, Dr. Brodie, Dr. Chapaton, His Honor, the Mayor, the President of the Police Commission, the Comptroller and Dr. Klein.

THE authorities of Harvard University have invited Sir Edwin Arnold to deliver a course of lectures to the students on subjects of his own selection.

THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION will meet at Evansville, Ind., September 24, 25 and 26, 1889.

THE AMERICAN PHARMACEUTICAL ASSOCIATION held a very successful convention at San Francisco from the 24 to the 29th ult. The following officers were elected: President, Emlen Painter, New York; First Vice-President, Karl Simmons, St. Paul; Second Vice-President, W. M. Searby, San Francisco; Third Vice-President, J. W. Eckford, Aberdeen, Miss.; Treasurer, S. A. D. Sheppard, Boston; Permanent Secretary, J. M. Maisch; Reporter on Progress of Pharmacy, C. Louis Diehl, Louisville, Ky.; for Members of the Council to serve three years, Loe Eliel, South Bend, Ind.; W. S. Thompson, Washington; John H. Dawson, of San Francisco. The next meeting will be held at Old Point Comfort, Va., the second Monday in September, 1890.

THE PRESBYTERIAN HOSPITAL at Philadelphia is the recipient of \$100,000 donated by Lady Courtright and to be used to found a Convalescent's Retreat. She has also given \$50,000 to the Hospital to build a male surgical ward and to endow two free beds.

EXPLANATORY.—It is due to the readers of THE JOURNAL to state that while the President's

Address and other matter pertaining to the meeting at Newport was in type, it was deemed advisable not to present them in the last issue of a closing volume, and thus separate them from all that was to follow in the new volume which was to commence with the next issue. It seemed better to issue the first number of the new volume three days in advance of the date assigned and thus present an unbroken series of papers, and that only four days later than they would have appeared in the previous issue.

## FOREIGN.

IN FRANCE the heirs of the late M. Chevreul have presented his valuable scientific library, numbering 10,000 volumes, to the Paris Museum of Natural History.

IN SWITZERLAND the profession is well organized. The Schweizerischer Aerztlicher Central Verein, Société Médicale de la Suisse Romande, and Società Medica della Svizzera Italiana held joint meetings at Berne on May 25.

IN GERMANY an Odontological Society has been organized in Berlin under the presidency of Prof. Busch. Drs. E. von Bergmann and von Esmarch have recently been honored with high appointments in the Sanitary Corps of the army. Dr. Curtius, of Erlangen, and Dr. Guttermann, of Göttingen, two young German Professors of Chemistry, have accepted a call from the faculty of the new Clark University of Worcester, Mass.

IN INDIA rain has fallen in the Gamjam district, and the number of deaths from cholera has decreased from 1029 to 865. Dr. Waddell, Deputy Sanitary Commissioner for Bengal, is investigating the question as to whether venomous snakes are anti-toxic. Dr. Patric Hehir, in his report on Cholera in the Chudder-Ghaut municipality, and referring to the pollution of the drinking water as the main cause of the epidemic, says: "While investigating the cause of an outbreak in the village of Kharatabad, I noticed a woman washing the clothes of her husband (who had died of cholera), in a large well from which several persons were actually drawing water for drinking purposes." Leprosy is on the increase.

IN ENGLAND there has been a meeting of delegates to make preliminary arrangements for organizing an International Congress of Hygiene and Statistics to meet in London in 1891. There

are 402 medical practitioners and 119 medical students on the roll of the British Medical Temperance Association. Dr. C. B. Radcliff, an eminent physician and an authority on nervous diseases, died recently in London. A feature of the *British Medical Journal* is the occasional column contributed by the Editor, entitled "Topics of the Day." The Charity Organization Society is about to petition the House of Lords for an inquiry in regard to the administration and organization of hospitals, dispensaries, and poor law infirmaries. The British Medical Association will hold its fifty-seventh annual meeting at Leeds from August 13 to 16. A new hospital for patients suffering from infectious diseases has been opened at Muswell Hill. At Cambridge University, Dr. W. H. Gaskell, University lecturer in advanced physiology, and Marshall Hall Prize-man for his researches on the nervous system, has been elected to a fellowship at Trinity Hall. The Prince of Wales leads the movement that the people of England shall give practical expression to their admiration of Father Damien by the erection of a monument to his memory at Molokai.

## SOCIETY PROCEEDINGS.

### American Medical Association. Fortieth Annual Meeting, at Newport, R. I.

#### *Section on the Practice of Medicine, Materia Medica and Physiology.*

FIRST DAY, JUNE 25, 1889.

The session was opened by an introductory paper on *A Review of Progress*, by Dr. F. C. SHATTUCK, of Boston, Chairman of the Section. A complete résumé of all later forms of treatment was placed before the Section. (See p. 19.)

DR. CHAS. G. STOCKTON, of Buffalo, read a paper *On the Passage of Portal Blood into the General Circulation, and its Probable Relations to Toxæmia*. This elicited quite a spirited discussion, in which some of the claims of the essayist were criticised, but ably answered by Dr. Stockton.

DR. G. R. MARTINE read a paper entitled *A New Plan for the Treatment of Pneumonia*, which was virtually the Veratrum Viride treatment. Discussion entered into by Drs. Hall and Atkinson.

DR. I. H. MUSSER presented a paper on *Some Clinical Aspects of Vomiting*, dwelling on the various forms of vomiting and their differential diagnosis.

DR. I. E. ATKINSON read an extensive paper on *Some of the Rarer and Graver forms of Cinchonism*. The discussion which followed was taken part in by the two classes of practitioners who advocated on the one side, and on the other deprecated the use of large doses of quinine.

DR. ROBERT T. EDES read a paper on *Hydro-nephrosis; Especially as Caused by Functional Disorders of Micturition*.

SECOND DAY, JUNE 26.

DR. FELL, of Buffalo, presented to the Section on Medicine an apparatus for keeping up respiration in narcotic poisoning. With this means he had saved four lives that would have been lost without the use of the apparatus.

DR. FRANCIS DELAFIELD read a paper on *Chronic Endocarditis*. The paper was thoroughly discussed by Dr. Pepper.

DR. WM. OSLER reported an interesting case of *Word Blindness with Hemianopsia*, together with a presentation of specimens and diagrams. Dr. Osler also exhibited specimens of brains, prepared according to the Italian method.

DR. JAMES TYSON, of Philadelphia, read a paper on *The Induction of Premature Labor in Bright's Disease Complicating Pregnancy*.

DR. VAUGHAN, in discussing the paper, agreed with the essayist in the main points except as to its induction in primipara. Establishing it as a rule to induce premature labor in such patients that have had similar experience previously. He treated by limiting the patient's diet and assisting elimination.

DR. ATKINSON insisted on this plan of treatment as soon as the mildest symptoms were manifested. The most frequent and dangerous cases are due to the contracted kidney.

DR. SCOTT gave the Section a review of his valuable and long experience.

DRS. CHAMBERLAIN, CARPENTER, TRUAX and NELSON added their arguments to the discussion.

DR. PRENTISS next called attention to the importance of the work in forming the Pharmacopœia of 1890.

Dr. Prentiss also moved that the Chairman of this Section be requested to offer the following resolution at the general meeting to-morrow (Thursday):

*Resolved*, That the President of the American Medical Association be authorized to appoint three delegates to the Convention for the Revision of the U. S. Pharmacopœia, which meets in Washington in May, 1890.

Carried.

DR. GEO. M. GARLAND's paper on *Raynaud's Disease*, with report of a case, was received with great favor. The presentation was rendered more interesting by the exhibition of illustrations.

DR. CARPENTER had seen the patient whose history was given in this paper, and treated him during the latter part of his life.

DR. SHOEMAKER treated on the new remedy, *Dioscorea Villosa*.

### THIRD DAY, JUNE 27.

DR. VAUGHAN opened the meeting with a paper on *The Etiology and Pathology of Typhoid Fever*. In it he presented a detailed history of all investigations and discoveries hitherto brought forward, and an enumeration of experiments made by himself.

DRS. WELCH and TYSON, in the discussion, dwelt upon the conditions necessary to establish the causal relation of germs and disease.

DR. JAMES C. WILSON read an elaborate paper on the *Prophylaxis of Tuberculosis*.

DR. HENICK, in the discussion, still doubted that positive proof of the contagiousness of tuberculosis had been presented.

DRS. CUTTER and WHITNEY entered into the discussion in the same spirit.

DR. COHEN was very happy in his remarks, occupying a middle position between those of Dr. Wilson, who ably defended his position in the concluding remarks.

DR. M. R. CRAIN presented a paper entitled *Toxic Agents in the Blood as a Cause of Diseases of the Nervous System*.

DR. W. L. SCHENCK offered *Some Thoughts on the Etiology, Pathology and Therapeutics of Phthisis Pulmonalis*.

DR. SOLOMON SOLIS-COHEN, of Philadelphia, read an excellent paper entitled *Food in the Treatment of Consumption*.

DRS. E. and J. A. CUTTER followed with an essay on *Trophopathy in the Fatty and Fibroid Degenerations: with Presentation of Case of Cure*.

### Section on Obstetrics and Diseases of Women.

#### FIRST DAY, JUNE 25, 1889.

DR. HORATIO R. STORER, of Newport, R. I., read a paper on *The Medals of Benjamin Rush, Obstetrician*.

Dr. Storer's paper calls forcible attention to the fact, that to Dr. Rush was owing the first suggestion, or rather prophecy, of obstetrical anæsthesia. He quotes various passages from Rush's work, which demonstrate that "he was, throughout, a skilful obstetrician. In the very title of one of his papers, he closely associates the pains of labor with its dangers, he announces that they can both be lessened, he recognizes that they are the potent cause of subsequent disease, and he teaches its prevention."

Dr. Storer particularly calls attention to the following passage of Rush: "I have expressed a hope in another place that a medicine would be discovered that should suspend sensibility altogether, and leave irritability, or the power of motion, unimpaired, and thereby destroy labor-pains altogether."<sup>1</sup>

The importance of this extraordinary interesting passage seems to have been recognized only by Channing, Gaillard Thomas, and Faget, of New Orleans. It was lost sight of entirely through the ether-chloroform controversy. Dr. Storer after exhaustive research, in which he has been aided by Dr. Toner, of Washington, fails to find other reference to it, and in this impression he is coincided with by Drs. Muudé, Chadwick, and Gaillard Thomas, to whom he had appealed as probably most familiar with modern obstetric literature.

Dr. Storer exhibited enlarged photographs of the two extremely rare medals of Rush, which are in his collection, and expressed the hope that they would be found of use in giving the correct features of the "American Sydenham" when his monument, undertaken by the Association, shall be raised, and that the paper itself might tend towards a better appreciation of the true merits of the man himself.

DR. W. W. POTTER, of Buffalo, N. Y., then read a practical paper on *Note on the Uses of Boric Acid in Gynæcic Practice*.

(See page 46.)

The next paper, by DR. HENRY O. MARCY, of Boston, on *The Inversion of the Uterus: Reduction by a New Method*, and the exhibition of instrument, was one of great interest and brought out a very complimentary discussion by Drs. Clark of Cambridge, Lusk and Cleveland of New York. This paper will be published in the next issue of THE JOURNAL.

DR. JOSEPH PRICE, of Philadelphia, read a paper entitled, *Series of Five Hundred Confinements in a Maternity*. Dr. Price described briefly the Maternity Retreat of Philadelphia, in which such brilliant results are made possible by the absolute system of cleanliness prevailing at that institution. As this excellent paper as a whole was but a brief summary of much labor, the reader must be referred to the paper itself as it appears subsequently in full in these columns.

This paper was discussed by Dr. Thomas Opie, of Baltimore, Prof. Lusk, of New York, and others, all agreeing in the main with the writer, and emphasizing strict antiseptic methods as a requirement of success in obstetrics.

DR. HENRY D. FRY, of Washington, read the next paper, his subject being: *The Application of Forceps to Transverse and Oblique Positions of the Head: Description of a New Forceps*.

The author advised strongly the application always of the obstetrical forceps to the biparietal diameter of the head without regard to its position in the pelvis, and presented forceps the construction of which makes it practicable to apply the instrument to the transverse or oblique position of the head.

Before the discussion was opened on the above paper another paper was read by Dr. W. S. STEW-

<sup>1</sup> "Medical Inquiries and Observations," 3d edition, iv p. 376.

ART, of Philadelphia, on *When should the Obstetric Forceps be Used and what Form of Instrument is Required?* A new forcep was presented by Dr. Stewart in which was involved the principle by which either blade may be applied first.

Dr. JOSEPH TABER JOHNSON, of Washington, opened the discussion. He said that Dr. Fry's paper had interested him very much, and although he had had no experience in the use of his forceps, he certainly should avail himself of the first opportunity presented to do so.

Dr. PARVIN, of Philadelphia, said that the instrument of Dr. Fry's for transverse and oblique positions was the revival of an old instrument, and he predicted that the result would be short-lived in the present case. He objected to Dr. Stewart's forceps because of the length and complication of the handles.

Dr. JOSEPH PRICE objected to Dr. Fry's forceps because he was sure that dangerous compression of the neck of the child would result from its use.

Dr. THOMAS OPIE, of Baltimore, then read a paper on *The Obstetrician as a Counselor*.

SECOND DAY, JUNE 26, 1889.

The following officers were elected for the ensuing year: Dr. W. W. Potter, of Buffalo, President, and Dr. Hoffman, of Philadelphia, Secretary.

The Address of the Chairman, Dr. WATHEN, of Louisville, was on the *Pathology of Ectopic Pregnancy and Pelvic Hematocele*.

He referred to the fact that nearly everything written on ectopic pregnancy prior to 1880 is of no real value. He treated his subject in the following order:

1. The ovum is never impregnated in the uterine cavity, and the conjugation of the male and female elements must take place before or just after the ovum enters the tube.

2. Ectopic pregnancy is always primarily tubal, with the possible exception of ovarian pregnancy. The tube usually ruptures before the fourteenth week into the folds of the broad ligament, or into the peritoneum.

3. Abdominal pregnancy cannot occur except as a result of primary or secondary rupture, and if the villous or placental attachments are destroyed the ovum immediately dies, because it cannot form secondary attachments to other structures.

4. If, in ruptures into the peritoneum, the ovum retains villous or placental attachments, it may be possible, under certain conditions, for the pregnancy to continue, though not probable. If the amnion is ruptured in the early months the embryo will die.

5. So-called interstitial pregnancy does not always rupture into the peritoneum; it usually does.

6. If we define pelvic hematocele as an encysted or confined tumor formed of blood, then intraperitoneal hematocele is not possible.

He treated the subject in detail, and gave many valuable facts in proof of the above propositions. In a general sense, he accepted the conclusions of Mr. Tait, but he differed with him in his belief that in normal pregnancy the male and female elements meet in the uterus, and that, in a healthy condition of the tubes, the spermatozooids cannot pass out to the ovaries. He claimed that the ciliated epithelium has no influence on the movements of the spermatozooids, but that they move by an inherent force, and may reach the ovaries through a healthy or a diseased opening. In his argument that primary abdominal pregnancy is impossible he says: "The ovum cannot form villous attachments until it is held immovably in the maternal structures, and this is not possible except in the tube or uterus. If the ovum fails to enter the tube it will soon perish in the abdominal cavity, for it cannot fix itself to the peritoneum, as this and surrounding structures are in nearly constant motion." He did not believe it has been positively proven that any of the specimens were ovarian pregnancy, for this could not be done except by a thorough microscopical examination of all parts of the gestation sac and the demonstration of a general distribution of ovarian stroma. The address was in every way creditable to its author, and the Section voted him a unanimous vote of thanks.

A paper was read by Dr. THEOPHILUS PARVIN, of Philadelphia, on *Casistry in Obstetrics*, which will appear in full in THE JOURNAL.

Dr. A. VAN DER VEER, of Albany, N. Y., read a paper on *Concealed Pregnancy, its Relation to Abdominal Surgery*.

This paper was based upon the study of seventy cases of abdominal section wherein pregnancy existed as an undiagnosed complication. A diligent effort had been made to obtain full histories of cases, and many prominent operators from all portions of the world had made contributions. Two complete tables were given, being twenty-six cases were pregnancy existed with fibroid, ten cases simple pregnancy, five cases in which the pregnancy existed in a rudimentary form of a bi-cornate uterus, and twenty-nine cases in which simple ovarian cyst alone existed. In the majority of the cases no symptoms of pregnancy are noted. Rapid growth and changes in the consistency of the tumor in fibroids was observed in nearly all of the cases. The physical signs of pregnancy, prior to the fourth month, may be either obscured or concealed by the presence of a fibromyxoma. Hydramnion as a complication of pregnancy led to abdominal section twice. It was clearly shown that the statement of unmarried women with abdominal enlargements must not be relied upon. The paper is certainly a valuable one upon this subject, and the conclusions to the point. Namely, That the probable diagnosis should be based upon the

physical signs contained in the notes of the case by the rational signs contained in the clinical history, and not by simple abdominal palpation, and the dim light of a pelvic examination. That whenever the slightest probability of pregnancy exists it should be fully explained to the patient and to her friends. That the necessity for operative relief, and the consequences of delay, or neglect, should be carefully stated to the parties interested before obtaining their formal consent to the operation. That it is the duty of every operator to report fully all such cases, that the methods of diagnosis may be improved if possible. That it is the duty of the profession at large to maintain that pregnancy may be absolutely concealed, especially prior to the fourth or fifth month, by other intra-abdominal conditions.

DR. W. H. PARRISH, of Philadelphia, read a paper on *Pelvic Abscess in the Female*, which will be published in full.

DR. JOS. TABER JOHNSON, of Washington, D. C., read a paper upon *Tetanus following Ovariectomy*. The Dr. gave the history of the case which formed the basis of his paper, she being a lady over 60 years of age, from whom he removed a sarcomatous tumor of the left ovary the size of a child's head. Patient convalesced unusually well for twelve days, when tetanus set in and she died three days later of lock jaw. Of this very rare complication of ovariectomy Dr. J. had collected from publications about fifteen cases, including ten cases collected by Dr. Parvin in 1877.

The infectious nature of the disease was discussed, and instances narrated where it had been communicated from animals, especially horses, to man.

The tetanus bacillus was shown to be the same in animals and in the human family, and the workers in abdominal surgery were warned against the possible contamination of their cases by the contagium emanating from tetanus, cases originating in either human or animal sources.

In the discussion Dr. Polk, of New York, complimented Dr. Johnson upon the practical value of his paper, and thought the warning against this new and, to many, unknown danger, a very timely and important one.

A paper was then read by DR. A. REEVES JACKSON, of Chicago, on *Injuries to the Bladder During Laparotomy*. Dr. Jackson's report included sixty-seven cases of injuries to the bladder gathered from the profession at large by means of a circular letter. The paper contained many valuable suggestions, which will appear in full when the paper is published in THE JOURNAL.

After Dr. Jackson's paper was read the discussion of all the papers of the afternoon took place, in which Drs. Polk, of New York, Joseph Price, of Philadelphia, Gordon, of Portland, Me., Baldy and Hoffman, of Philadelphia, and Dudley, of New York, took an active part.

The proceedings of the third day included a paper by Dr. A. B. Carpenter, of Cleveland, O., on *Alexander's Operation: with a New Method of Securing the Round Ligaments*; and one by Dr. Augustus P. Clarke, of Cambridge, Mass., on *Chronic Cystitis in the Female*.

### *Surgery and Anatomy.*

FIRST DAY, JUNE 25, 1889.

DR. N. P. DANDRIDGE, of Cincinnati, Chairman, of the Section, delivered an address on *Surgical Interference in Fractures of the Spine*.

(See page 37.)

The discussion was opened by DR. WM. H. PANCOAST, of Philadelphia, who cited several cases similar to those given in the paper, and reported post-mortems on hanged criminals whose death was caused by shock and not by fracture or dislocation of cervical vertebræ. In one criminal a vertebra was broken but not displaced.

In the absence of Dr. W. W. Keen, of Philadelphia, the paper on *Surgery of the Lateral Ventricles of the Brain* was omitted.

DR. H. H. SMITH, of Philadelphia, read a paper on *Concussion of the Spine in its Medico-Legal Aspect*. He said a medical man should not act both as medical expert and medical adviser for any corporation, and gave forty-nine cases of concussion of spine or "railway spine," of which thirty-six were real or probable deceptions; mostly cases of simulation and one case of substitution.

1. Can any force be so supplied as to cause real concussion of spinal cord? Yes, but it is not a common occurrence.

2. How are the normal functions of the cord disturbed by such injuries?

a. Anæsthesia, hyperæsthesia, etc.; b. Motor disturbances; c. Vaso-motor disturbances; d. atrophic changes.

3. Pathological changes.

If the disturbance is functional it may be cured. Neurasthenia can produce all the symptoms usually attributed to concussion. Molecular changes may be produced by severe shaking of cord without any injury to the canal. Injury to cord in any accident is followed very quickly by the symptoms, and we must look with suspicion upon cases where spinal symptoms are not developed for several weeks or months.

Conclusions: 1. Concussion of the spinal cord is no longer a matter of doubt. 2. Pathological changes noted in the molecular condition may be due to other causes. 3. There is a possibility of preëxisting spinal disease. Therefore, *no physician* should go into court and swear that a man has spinal concussion due to a certain injury and permanent.

DR. HERBERT JUDD, of Galesburg, Ill., read a

twenty-five minute paper in which he set forth the same general conclusions as Dr. Smith.

DR. WM. BRODIE, of Detroit, Mich., cited two cases, in one of which his testimony was for the plaintiff; in the other, against. The jury gave the plaintiff heavy damages in both cases. Conclusions: Immediately after a man is hurt the railroad surgeon should advise the company to settle.

DR. B. A. WATSON, of Jersey City, N. J.: Spinal concussions are not so frequent as would seem from court decisions. I have observed as the most frequent injuries following railroad accidents: 1. Hæmorrhagic infarction in lungs. 2. Lacerations of liver, spleen, lungs or kidneys. 3. Rupture of blood-vessels and bladder.

DR. C. B. PENROSE, of Philadelphia, being absent, the Secretary read a paper in consonance with the preceding discussion.

DR. J. H. MURPHY, of St. Paul, Minn., said: Erickson has cost the railroads thousands of dollars. He cited several cases of malingering.

DR. WM. H. PANCOAST, of Philadelphia, said: The question under discussion has two heads: 1. Is there such an injury as spinal concussion? 2. Are there malingerers who assume the symptoms? He discussed clearly these two questions, ending with the conclusion that many railroad injuries can be adjudicated, and the real sufferers properly compensated, by the judicious surgeon acting as the mediator between the opposing lawyers to the honorable satisfaction of both parties.

DR. MAURICE RICHARDSON, of Boston, read a paper on *Surgery of the Peripheral Nerves*, illustrated by black-board drawing. He said: Neurotomy is the proper treatment for wryneck, and gave new landmarks for reaching the spinal accessory by making an incision on the anterior border of mastoid parallel with course of muscle. In cases of nerve suture he had used both catgut and silk, but prefers silk if it is aseptic. In most cases there is return of motion and sensation; in no case has healing by first intention been observed. Many interesting cases cited, most of which were successful.

DR. WM. H. PANCOAST, of Philadelphia, made a spirited speech, claiming the honor of the first neurotomy of the fifth pair of nerves for his distinguished father.

Drs. Dever, of Philadelphia; W. O. Roberts, the Secretary of Section; S. C. Gordon, of Portland, Me.; and Burns, of Philadelphia, followed in the discussion, all citing cases from their practice in consonance with the ideas of Dr. Richardson.

Drs. C. C. Hunt, Dixon, Ill., and E. H. Bradford, Boston were absent.

Dr. Carpenter's paper on *Pathology and Treatment of Chronic Sciatica*, was deferred till the second day.

## SECOND DAY, JUNE 26.

DR. C. B. PORTER, of Boston, read a paper on *Ectroversion of the Bladder*.

He said: Whatever operation is chosen the free exit of the urine is necessary to success. A case was exhibited. Girl, æt. 8 years, had complete ectroversion; congenital gap at symphysis pubis 3 inches; mucons membrane of bladder and vagina freely exposed to air and friction of clothing; suffering and uncleanness extreme. Operation Jan. 11, 1889, consisted in making large pear-shaped flap, hinged at mons veneris, and extending to umbilicus. This flap was turned down, covering in the bladder, with the skin surface making the anterior wall of bladder. The external raw surface of the flap was covered by two half-size flaps cut from the inguinal region and turned around toward the median line. The surface exposed on anterior aspect of abdomen was drawn together by sutures; the other two surfaces healed by granulation. A hot dressing was applied. Three months after the operation the girl joined her playmates, relieved of all pain and wearing a shield between the legs. There is always incontinence of urine in these cases.

In the absence of the author, DR. C. C. HUNT, of Dixon, Ill., the paper on *Suspension and Extension in Treatment of Sciatica*, was read by title.

DR. W. T. BRIGGS, of Nashville, Tennessee, read a paper on *The Choice of Operations for the Removal of Urinary Calculus*. He said: In children under 16, the cutting operation should by all means be chosen; after puberty, litholapaxy. In old age mortality is greater in both operations, but crushing in the hands of a skilful operator is better. The composition of the calculus is important. Large uric acid calculi, or oxalic calculi are hard to crush, and better be cut for. Stones return with less frequency after litholapaxy. The size and toleration of the urethra are important factors. Lithotomy should be chosen in the following cases: 1. Children; 2. Large and hard stone; 3. Encysted stone; 4. Indurated and crooked urethra; 5. Prostatic enlargement; 6. Prostatic overgrowth; 7. Prostatic enlargement with putrid urine; 8. Tumor of bladder; 9. Chronic cystitis.

Litholapaxy should be chosen: 1. For adults; 2. In cases of soft stones; 3. Where urethra is of good calibre and tolerant. The supra-pubic lithotomy may be performed in cases where stone is too hard to be crushed, and too large for perineum. The raphe is nature's field for incision, and the medio-lateral incision is almost devoid of any danger to life. He reported 186 cases in his practice with three deaths.

DR. A. T. CABOT, of Boston, read a paper on *The Choice of Operations for Stone in the Bladder*. The best operation is the one which is followed by the fewest deaths; provided there is

no permanent disability. The statistics of recent years make litholapaxy and perineal lithotomy of equal value for children. During adult life litholapaxy is rather safer than perineal lithotomy and in old age it is much safer. In all cases supra-pubic lithotomy should be resorted to last, for its death-rate is from three to six times as great as either of the others. He reported forty-seven cases: Litholapaxy forty-two, deaths two; lithotomy four, deaths one; supra-pubic lithotomy one, death one.

DR. DUDLEY ALLEN, of Cleveland, Ohio, read a paper on *Litholapaxy in Children*. Dr. Allen thinks litholapaxy is better because the public is not afraid of it. They delay the cutting operation too long often. After litholapaxy the patient is confined to his bed 5.7 days, after lithotomy 17.6 days. The return of stone is no more frequent in litholapaxy than in lithotomy. If stone returns, the patient will, as a precaution wash the bladder for several days after the operation.

DR. J. W. S. GOWLEY, of New York, read a paper on *The Choice of Treatment of Urinary Concretions*. He said: Lithotripsy at several short sittings without anesthesia is devoid of the often serious complication of ether-nephritis; it does not incapacitate the patient from work during treatment. It is never followed by traumatic acute cystitis, and there is no greater tendency for return of the stone. However, the proper choice of treatment of urinary calculus can only be made after a careful study of the case.

SIR JAMES GRANT, of Ontario, said that as far as his experience went he much preferred lateral lithotomy, and spoke in very complimentary terms of the advances in surgery made by the surgeons of the United States.

DR. TREMANE said that suprapubic lithotomy is an American operation. He has performed perineal lithotomy on eighteen persons in boyhood. They grew up around him, all of them got married, and but one of them had children. This is significant. Sir Henry Thompson agrees with him that after 5 years the suprapubic operation is free of most of the disadvantages of perineal lithotomy.

DR. W. H. PANCOAST, of Philadelphia, urged the importance of recognizing the difference of irritability of the bladder; the extreme irritability of some bladders making lithotripsy and litholapaxy dangerous in those patients.

DR. R. T. MORRIS, of New York, read a paper on *What Dressing Shall Lie Next to the Wound?* He recommends, in fresh wounds, the use of Lister's protective oiled-silk. On a large granulating surface use peroxide of hydrogen freely to make the wound and the adjacent parts aseptic, cover with oiled-silk, apply dry, absorbent dressing that may remain from one to four weeks. Whether bichloride gauze is used or absorbent cotton is immaterial.

DR. H. O. MARCY, of Boston, said he agreed with Dr. Morris in his treatment of granulating wounds, but in fresh incised wounds he uses no dressing, simply drying the surface and painting with iodoform collodion.

DR. W. H. PANCOAST, of Philadelphia, reported the very successful use of iron-dyed silk both as dressing and as sutures.

Drs. M. A. Crain, of Rutland, Vt., I. N. Quimby, of Jersey City, N. J., and Thos. H. Manley, of New York, continued the discussion.

DR. J. C. WARREN, of Boston, read a paper on the *Management and Treatment of Large Hernia*.

He had used on a very large scrotal hernia a bag with inelastic exterior and elastic lining. Inflating space between bag and its lining by means of a fountain syringe, a steady pressure was produced upon all surfaces of the hernia except the pedicle. The result was successful. In old men who fear a cutting operation, an inelastic suspensory bandage has been used successfully. He concluded by advising the gradual reduction of a hernia by pressure of air, water or rubber. It is not a new treatment, but its value is not generally recognized.

DR. H. O. MARCY, of Boston, read a paper on *Radical Cure of a Hernia by use of the Aseptic Animal Suture*.

He reported fourteen cases, exhibiting the hernia sacs removed, stuffed with cotton and preserved in alcohol. The requirements of the operation are: Dissect out sac, reduce gut and omentum, draw down sac, ligate it, the ligated neck retracts within the internal ring. Use animal sutures in such a way as to *make the canal oblique*. The obliquity of the canal is of great importance; it is nature's safety valve—the greater the internal pressure, the tighter the valve. Close the external wound with deep sutures (animal) without drainage and dress with iodoform collodion. Catgut sutures and ligatures may be used, but the tendon suture is his choice.

DR. WARREN, of Boston, does not believe in animal sutures. Uses silk or linen, and places them in such a way as to make a knuckle of peritoneum over the internal ring.

DR. J. B. DEEVER, of Philadelphia, read a paper on *The Radical Cure of Hernia*.

He reported several cases. One case complicated with vesicle hernia, where the bladder was mistaken for a second hernia sac containing a loop of intestines. It was ligated and resected. Within 24 hours the patient died in collapse, the ligated bladder having escaped from the ligature and the urine and blood passed into the abdominal cavity.

DR. C. W. DULLES, of Philadelphia, read a paper on *Properitoneal Hernia*.

The paper showed wide research, and the author made a new classification of this rare form of hernia.

A general informal discussion then ensued on the subject of *Treatment of Hernia*. The following members took part: Drs. T. H. Manley, of New York City; Dudley Allen, Cleveland, O.; E. W. Cushing, Boston; A. P. Clark, Cambridge, Mass.; H. J. Herrick, Cleveland, O.; W. H. Long, United States Marine Hospital, Cleveland, O.; R. T. Morris, New York City.; L. W. Steinbach, Philadelphia; W. H. Pancoast, Philadelphia; Murphy, St. Paul, Minn.; H. D. Didama, Syracuse, N. Y.

### THIRD DAY, JUNE 27.

DR. THOMAS S. K. MORTON, of Philadelphia, read a paper entitled *Some Further Considerations and Statistics of Abdominal Sections for Traumatism*.

He said severe abdominal injuries may exist without shock. Emphysema around a wound is not conclusive evidence that the intestine is wounded. A sufficient indication for laparotomy is the presence of a wound perforating the abdominal wall. Shock is a contra-indication unless it be from hæmorrhage. The earliest possible moment after the injury should be chosen for the operation. The incision should be median always, unless the injury be very far from median line, and the failure to readily find or repair the internal wound should drive the operator immediately to the median line.

Wounds of the kidneys, liver and spleen should be drained—a small glass tube is best. The stomach should be washed out to avoid vomiting. Rectal alimentation when the alimentary tract has been wounded, unless that wound be in the rectum itself. Though he could not concede to hydrogen gas all that has been claimed for it, he could claim something new for it—its injection into the bladder to discover wounds in the walls of that viscus. When we find that thirty-six deaths have occurred, in the number reported to him from *delay*, we ought to take that as a pertinent suggestion.

DR. J. W. PRICE, of Philadelphia, read a paper on *Pelvic Surgery by Abdominal Section: its Past, Present and Future*.

He said: Aseptic surgery may be obtained without the introduction of chemical antiseptics into the wound. Cleanliness, water and neat surgery are the best antiseptics. In incipient peritonitis use saline cathartics. Begin operative procedure early. Procrastination is not only the thief of time, he is the servant of death. Gonorrhœa may be the cause in a woman of one of the most serious pelvic diseases—pyosalpinx. He doubts that electricity in treatment of pelvic disorders has the value that is claimed for it.

DR. J. M. BALDY, of Philadelphia, read a paper on *Peritonitis*.

He said: That peritonitis is idiopathic and a distinct disease, is denied by many. He had

never seen a case where a cause could not be found. This being the case narcotics are not indicated in its treatment, except sufficient anodyne to take the edge off the pain. The paramount indications for treatment are: First, drainage, and second, depletion, both of which may, in many cases, be effected through the alimentary canal by saline cathartics. Magnesium sulphate  $\bar{5}j$  to  $\bar{5}j$  to get twelve or fifteen profuse watery stools. Salines cannot be indiscriminately used. Study the case. Some require surgical interference. In treatment by purgation, the prognosis can be made in 48 hours, and surgical procedure instituted in some cases. Chronic peritonitis can be best treated by the surgeon even when the disease is tubercular.

The paper by DR. CHAS. B. PENROSE, of Philadelphia, on *Drainage in Abdominal Surgery*, was read by title.

The paper by DR. M. PRICE, of Philadelphia, on *A Plea for Early Abdominal Work*, was read by title.

DR. N. B. CARSON, of St. Louis, read a paper on *Chylous Cyst of Mesentery with Report of a Case*.

He reported a case, an interesting one, which was diagnosed by palpitation and aspiration. Operation: Incision, drainage, dressing, iodoform gauze; result, perfect. Origin of chylous cysts: 1. Thoracic Duct. 2. Receptaculum chyli. 3. Mesenteric glands. Of seven cases reported, one died. He advises operation as soon as the tumor inconveniences the patient.

The following members took part in the interesting discussion: Conservative—Drs. E. Griswold, Sharon, Penn.; Quimby, Jersey City; and Lee, of Chicago. Radical—Drs. R. T. Morris, Steven Smith, and T. H. Manley, of New York; and J. B. Deaver, of Philadelphia.

DR. ADDINELL HEWSON, of Philadelphia, read a lengthy and amusing paper on *The Use 25 Years Ago of Polarity for Locating the Whereabouts of a Lead Bullet Deeply Imbedded in the Body*.

DR. THOS. H. MANLEY, of New York, reported *A Unique Case of Fractured Exostoses of the Pubis*.

Diagnosis obscure, abscess found pointing in Scarpa's triangle. No apparent cause, pus fetid. Operation: Incision and drainage, with exploration for offending object. Post mortem discovered upon the brim of the pelvis an exostoses which had become dislodged from its connection with the pubis, thus becoming a foreign body and the origin of the abscess, which was a multilocular one, and extended from the popliteal space to the origin of the psoas muscles. The form of the exostosis suggests that it is a reduplication of the pubic bone. The pyogenic membrane was very dense and effectually protected the system from sepsis. If we had not operated the case might have spontaneously terminated favorably.

DR. ROBT. NEWMAN, of New York, read a

paper on *Electrolysis in the Treatment of Stricture of the Rectum*.

He cited a number of cases which were cured or improved. Conclusions: 1. Electrolysis in the treatment of stricture is not a panacea, and it will probably fail if the stricture is due to carcinoma. 2. Electrolysis will give improvement in rectal strictures where other methods have failed. 3. Electrolysis cures a certain class of cases better than other methods. 4. There is the best chance of a cure in a fibroid stricture. 5. Use a metal bulb with flexible stalk.

FOURTH DAY, JUNE 28.

DR. CHAS. DENISON, of Denver, presented *A New Rib Cutter and a Case of Resection of Ribs for Drainage of a Pulmonary Cavity*.

He reported a case of pulmonary abscess, associated with tubercular infection, opening interiorly and discharging  $1\frac{1}{2}$  pints of pus daily. Operation: Resection and incision. Treatment: Drainage, injection of an antiseptic wash and dressing, after filling the abscess cavity with salol solution 10 per cent in liquid vaseline. Result: After a few months patient returned to hotel clerkship at a high altitude in mountains, feeling well and weight increasing. Abscess cavity much decreased in size.

He exhibited a new and ingenious instrument, of his own invention, which combines a periosteum lifter and a rib cutter, works easily and quickly, cuts a smooth surface and is not costly.

DR. J. O. WHITNEY, of Pawtucket, R. I., said: Empyema and pulmonary abscess are to be treated on the general principles which have governed them for years: Drain, but, as a rule, do not inject disinfectants.

Discussion was continued by Drs. S. H. Weeks, of Portland, Me., and J. L. McComas, of Oakland, Me.

DR. J. B. HOPKINS, of Philadelphia, read a paper on *The Absorption of Dead Bone*.

He gave a history of several experiments in which dowels of sterilized dead bone were driven into holes drilled in dog femurs. The dogs were subsequently killed at varying lengths of time after the operation, and the gross and microscopic appearances studied.

The following conclusions were reached: 1. When sterilized dead bone is placed in close contact with the living bone, it will undergo absorption or organization. 2. The process goes on most rapidly during the period between the third and eighth weeks. 3. When sterilized dowels of dead bone are used for mechanical service they may be relied upon for four to six weeks.

Discussion followed by Drs. Quimby, of Jersey City; J. O. Whitney, of Pawtucket, R. I.; and J. L. McComas, of Oakland, Me.

DR. J. G. CARPENTER, of Stanford, Ky., read a paper on *Pathology and Treatment of Chronic Sciatica*.

The author believes in trying medicinal agents first and resorting at last, in case of their failure, to surgical interference in the form of nerve stretching. The after treatment consists in keeping the limb stretched for a few days, followed by extension by means of splints or plaster of Paris boot for three to six weeks. The limb should be bandaged to obviate swelling.

A paper on *The After Treatment in Cases of Abdominal Section* by DR. L. S. MCMURTRY, of Louisville, Ky., was read by title.

A paper on *Cranial Surgery*, by DR. H. O. WALKER, of Detroit, Mich., was read by title.

An abstract of the paper on *The Surgery of the Spine*, by DR. J. W. WHITE, of Philadelphia, was read by the secretary. Spinal trouble which may necessitate surgical interference: 1. Traumatism. 2. Caries. 3. Neoplasms. It is customary and proper in deciding upon any serious surgical procedure, involving risk to life, to consider well the prospects of the patient in the event of non-interference, and to be largely influenced by them. This principle is eminently applicable in cases of spinal surgery.

#### *Section on State Medicine.*

FIRST DAY, JUNE 25.

The first paper read was on the subject of *International Comity in State Medicine*, by Dr. John B. Hamilton, Surgeon-General U. S. M. H. S. Dr. Hamilton took as his text a portion of the resolutions recently adopted at the last Quarantine Convention held in this country, viz: the one in Montgomery, Alabama. The portion referred to reads as follows: "Resolved that this Conference is of opinion that it is a duty devolving on all nations, to take measures to eradicate any plague centre from their territory, and that the existence of plague centres is a menace to all other nations, and that our State Department be requested to take measures through proper diplomatic channels, for the conveyance of this opinion to the Governments deemed obnoxious to the opinion as herein expressed."

Dr. Hamilton made a strong plea for the extension of such action, and at the close of his paper, upon motion it was resolved that the resolution of the Montgomery Sanitary Association be adopted and transmitted to the general body of the Association.

DR. W. C. RIVES, of New York, read a paper on *The Importance and Essential Needs of Local Boards of Health*. This paper was an admirable plea for the extension of efficient sanitation, by means of local boards of health.

DR. HIBBARD, of Indiana, remarked that there is always a temptation to lay out too extensive a programme, and thus defeat the object arrived at. Action in the direction suggested should be con-

formable to and commensurate with the environments and conditions present.

DR. SMART, U. S. A., added but a word to the discussion, saying that he believed in the utmost energy.

DR. MORRIS, of Baltimore, referred to the Sanitary Association of Newport, which comprises such able sanitarians, and which yet permitted the existence of unsanitary closets in public places. For his part he is greatly interested in good plumbing everywhere.

DR. STORER, of Newport, arose to explain that while the Association was aware of the conditions referred to, it found some of them nevertheless, beyond their jurisdiction.

DR. N. S. DAVIS, of Chicago, read a paper on *The American Medical Association and its Relations to Public Health*.

The reader pointed out the work done by the Association since its inception. It began with the matter of the registration of vital statistics shortly after the founding of the Association. Next the adulteration of drugs received their attention. In both directions they succeeded in procuring valuable legislation. Later on, drainage, street cleaning, water supply, the use of disinfectants, and the effects of tea and coffee in children, all received their attention. Next they took up the study of epidemics. In 1850 a report was made on sources of typhus fever, with the necessary remedies. Valuable reports were also made on the subject of cholera. In 1851 the States were divided into eight groups, and in 1852 reports on epidemics were received from the groups. The sanitation of ships also received attention. Up to 1859, indeed the reports of the Association on the various subjects of sanitation and State Medicine, were most extensive, the reader himself being amazed to find that they formed nearly one-third of the bulk of the transactions during the years included. In 1859, at Dr. Lindsley's suggestion, five Sections were established, from one of which arose the Section of State Medicine of to-day. From 1847 to 1882, we find in the Transactions of the Association the very best record of epidemic diseases to be found. The influence of the Association was reflected upon the State and local societies, and it even led to the formation of new organizations, especially State and local boards of health. To-day we have in THE JOURNAL a most valuable agency for the propagation of the work that has been so well done by the Association.

DR. MORRIS, of Baltimore, took exception to the claims of Dr. Davis for the Association as the chief agent in securing the reform alluded to. He finds in the Association comparatively few active sanitarians, whereas in the American Public Health Association they have not only medical sanitarians but also architects and engineers.

DR. SMART, U. S. A., rose to say that Dr.

Davis claims that this Association is the father of the latter, and therefore entitled to credit for the deeds of the son.

DR. LINDSLEY, of Ohio, regretted that the Association had not of late years maintained the reputation which it had established so many years ago in the field of sanitation.

GEO. E. WARING, Esq., of Newport, read a paper on *Modern Sanitary Conditions*.

Mr. Waring felt confident that, by improved sanitary measures, the death-rate in cities could easily be reduced from 18 to 12 per mil., or, in other words, 365,000 lives could annually be saved. To accomplish this it is necessary to remove the organic waste of life before putrefaction occurs. This involves merely matters of drainage, garbage removal, improvement in water supply and increase of elevation.

DR. BAKER, of Lansing, Mich., said that there were diseases that could not be stopped by improved sewage and water supply. These diseases, such as scarlet fever, diphtheria and small-pox, are to be dealt with by legislation and disinfection. By these means it will be possible to reduce the death-rate even below Mr. Waring's limit.

DR. HIBBARD, of Indiana, thought that both methods should go hand in hand, for it is impossible to secure disinfection without engineering.

(To be concluded.)

## FOREIGN CORRESPONDENCE.

### LETTER FROM CAIRO, EGYPT.

*The Sanitary Condition of India and its Teachings.*<sup>1</sup>

In our last article we gave an account by an eye witness of the normal sanitary condition of a native hamlet in the suburbs of Calcutta, while no epidemic was raging. We now propose to lay before our readers an account of a visit, in December, 1887, to an Indian cholera stricken village also in the suburbs of Calcutta, in order that we may profit by the lessons taught us by the sad narrative. The epidemic here described is only part of that cholera epidemic, which has been spreading over the length and breadth of India since last year, and which is now raging in all its intensity in the Punjab. As all our readers know, India is the hot-bed of cholera, where it is always present in its endemic form, and where every three or four years it assumes an epidemic character, when it threatens to spread not only over India, but to every part having communication with that country. The destroying angel passing over the land of the Pharaohs and smiting the first-born in every Egyptian household, cannot have produced a more heart-rending

<sup>1</sup> Written for the "Arabic Medical Journal" and communicated to us through Dr. Joseph Jones, of New Orleans, La.

scene than the one now presented, on a smaller scale at Hathibagan, a suburban village, not more than a quarter of a mile from the centre of Calcutta. There within an area of small compass, more than twenty families, are each bewailing the death of some member or members of their family. The sound of the dirge and lament is heard at nearly every door, for within the last few days cholera has visited house after house, carrying with it sorrow and ruin, and panic. People are hurrying their dead to the burial and burying grounds, while others are fleeing for safety from the place. Among the refugees are not a few who have fled too late, only to be struck down on the roadside. Custom and apathy have so ordered that no pitying eye takes note of these things, no helping hand stretches forth succor to the suffering people in their affliction. Hopelessly left to shift for themselves they die in all the horrors and pangs of a cholera death. But this is not all. The moral insensibility which distinguishes the authorities in their attitude towards the sufferings of the inhabitants is only surpassed in permitting the causes of the pestilence to remain unremoved. The sanitary condition of the village has, out of India, no parallel in the civilized world. There are tanks supplying the inhabitants with drinking water and at the same time receiving the contents of their latrines, ditches full of the blackest and most putrid of mire, the soil soaked with the foulest and most noxious of filth, while the air is laden with impurities and redolent with stinks. Literally the place is a vast cesspool; air, water, soil are alike poisoned. Here the external and most potent causes of disease are in full play and germ, and ghastly indeed are the effects. Cholera, the child of filth, revels in its home, gaining in strength and vitality until conditions arise which shall give an opportunity of leaving its native soil, and visiting other places and countries congenial to its tastes. Doubtless the authorities will declare that the endemic or epidemic is due to seasonal influences, and that the deaths are not more than usual. This apology has ever and at all seasons been a convenient cloak for inaction; but how long is the truth to be suppressed for the ease of the authorities? Seasonal causes are myths of a by-gone day, and must give way to the irresistibly large accumulation of facts which evidence that polluted soil, polluted air, and polluted water, are alone a means of nurturing this fell disease, and that the removal of this pollution is alone the remedy. How long are the inhabitants to be deprived of a pure water-supply, of drainage, and of measures of cleansing, which are among the ordinary necessities of healthy aggregate life? It is idle to speak of the filthy habits of the people when the ordinary means whereby they can be clean are not placed within their reach. If municipal commissioners will not supply these three wants

to their constituents, no amount of education or lecturing will ever effect a change. The change must come over those who are in municipal power—that is from those who are in authority. At the present time the sanitary condition of the suburbs of Calcutta is an outrage on humanity, a satire on civilization, and a disgrace to all concerned.<sup>2</sup>

The closing words of the above report are even more trenchant than we dare use towards our authorities, how ever much tempted to do so. Now what can we Egyptians learn from this picture of the sanitary condition of our neighbors? What about the air we breathe? What about the soil on which our habitations stand? What about our drinking water supply? True, we have not cholera to deal with, unless when it is imported, but we have other death producing diseases always present, that are equally dependent for their existence and propagation, on what feeds cholera and other contagious diseases. It is not true that the air in and about the majority of our dwellings is pestilential; and have we not evidence enough that the soil is saturated with filth, and is becoming more and more so every day? As to our drinking water: if we have no means of showing the high Nile water, for about three months in the year we have to drink what may be truthfully designated sewage water, while, during the other months of the year the river is only comparatively pure by reason of the abundance of water, which helps to multiply the bad effects of the organic matter thrown into the Nile by the natives, for there is no sacredness attached to it, as gold, whereby it was kept undefiled. We have heard a great deal lately about the excessive death-rate throughout Egypt, but more especially in Cairo, and it may well attract our attention and draw out our concern. What are the best means to be adopted and are they being used? In other departments of the Government service we hear of great projects proposed and attempted at a great cost to the State, but the Public Health of Egypt is, in many respects, like the Public Health of India, left almost out of count, although disease and death threaten the very existence of such a small nation as this is.

India, with its population of 300,000,000, can afford to be well purged of its extra population by keeping up its sanitary condition, but this is not the case with Egypt, which is, at this moment, suffering from scarcity of tillers of the soil. There is no lack of immigrants, but none of them can replace the fellaheen. The cultivation of laborers ought then, one would think, to attract the attention of our political economists a little more, even than the cultivation of cotton and sugar cane. We question very much whether this is the case, but the shoe will pinch more

<sup>2</sup> *Journal of the Health Society for Calcutta and its suburbs*, Vol. iv, Part 1, 1888.

tightly some of these days, if some serious, well digested sanitary measures are not speedily adopted and carried out. There is a remarkable similarity between Egypt and India in the sanitary conditions, and in the apathy of the authorities, as to sanitary questions that involve the health and stability of the native population. One has only to walk through our cities and villages to be sensibly assured of the pollution of the air and soil, and in nine cases out of ten, that pollution is far more intense inside the houses of the natives than it is in the streets. Even the European houses are not exempt from unsanitary smells that might easily, by proper ventilation, be carried off and disinfected in the open air before destroying the health of the inmates. We read of the filthy water-supply in India, and of its deleterious effects on those who drink it, and we are not astonished to find that an impure water supply in Egypt is, accompanied by a high death-rate. Just look at those green stagnant pools at low Nile, that surround the Egyptian villages—that receive the filth and washings of the villages, and at the same time serve as a water-supply for man and beast. Can it be wondered at that the native population is dying out by a slow process of blood poisoning? Here there is no lack of polluted air, polluted soil, polluted water supply, and these, combined with the excessive heat of summer, ignorance and crime, make our demographic statistics, simply deplorable. The present sanitary condition of India has been designated an outrage on humanity. This may equally be said of the sanitary state of Egypt.

Surely things are not going to remain as they are. It becomes more and more evident, every day, that a Minister of Public Health is urgently needed in the Council of Ministers. There is no lack of intelligent and well-digested sanitary measures to be carried through, but as they are not immediately remunerative they are pigeon-holed and remain a dead letter! We have raised our feeble voice in the cause of sanitary reform, and we have indicated some of the ways by which the health of the people might be improved. As far as the climate is concerned little requires to be done, as it is so excellent. The heat of summer is, no doubt, some years excessive, and children suffer from the effect it has on their milk food, and many die from summer diarrhœa. This could be controlled somewhat, if the people were less ignorant and knew more about the proper preparation of food for the delicate stomachs of their children. The cold of winter does not last long, so that chest disease is not common among the natives, but we have seen many cases that would have better health if they had more clothing. We consider that a little more education would enable the natives to intelligently combat the evils arising from the climate. We think that

it is the duty of the Government to take the advice of its Sanitary Department as to the laying out of towns and villages, and as to the construction of individual houses, so as to secure pure air for its people to breathe. Many of the wild beasts have better dens to live in than the Egyptians have houses. The honey-comb principle, on which the houses of the villages are built, is entirely wrong. This could be rectified without much trouble, as they are but crude brick huts at best.

The Government is certainly responsible for a pure water-supply for man and beast, all the year round, and it would be wise, in fulfilling this duty, to make arrangements beforehand for carrying off the waste. When that is done, we shall have no more of the green stinking ponds around the native villages. At this moment Cairo is supplied with an abundance of water, but the sewers have been destroyed, so that, unless something is substituted for them soon, we shall have our streets flooded, if nothing worse befall us. We are desirous to see the Public Instruction and Sanitary Department in a more flourishing condition.

J. A. S. GRANT (BEY).

---

## MISCELLANY.

---

MARRIED, June 26th, at the home of the bride at North Brookfield, N. Y., by Rev. W. T. S. Lumbard, Howard F. Hubbard, M.D., of Verona, Oneida Co., N. Y., and Miss Geraldine L., daughter of Gilbert Birdsall, M.D., of North Brookfield, N. Y.

THE BROOKLYN THROAT HOSPITAL was formally opened on the 19th ult.

GEORGIA STATE MEDICAL ASSOCIATION.—At the annual meeting of this Association held at Macon, recently, the following were elected officers for the ensuing year: President, Dr. J. S. B. Holmes, of Rome; First Vice-President, Dr. R. O. Ingram, of Montezuma; Second Vice-President, Dr. P. R. Cortelyou, Marietta; Censor, Dr. G. W. Mulligan, of Washington; Orator, Dr. W. F. Westmoreland, of Atlanta.

PERSONAL.—Dr. J. M. Fox, formerly of Troy, N. Y., but now a resident of London and an M.P., will return to this country again and locate either in Albany or New York. Dr. Joseph P. Ross, a well-known physician of Chicago, is seriously indisposed. Cairo, Ill., has erected a handsome monument to the memory of Dr. Roswell Waldo, at Mound City, in recognition of his services in the yellow fever epidemic in 1878.

THE SANITATION OF THE LAUNDRY.—In speaking of this subject *The Lancet*, in the interest of the general public, says: A possible source of danger to health, and one which may, upon occasion, become the centre of incalculable mischief, is the laundry. The absence of any regulating authority, and the lowly condition of many of the proprietors of these establishments, render them particularly liable to faults of management; while the necessity which the dwellers in town are under of giving out their laundry work creates a limitless demand. It becomes, therefore, a matter of importance that from

time to time the warning voice should be raised, and the public put upon their guard respecting the lurking harm. A certain, even a considerable, risk must at the very best attend the institution of a common laundry. No readier method of disseminating the germs of infectious disease could well be devised than by the intermingling of wearing apparel, and where this intermingling takes place the use of antiseptics can afford no more than an untrustworthy and insecure protection from the risks of contamination.

Hence, the very safest plan is to arrange, where possible, for the laundry work to be done at home, and by resident domestic servants. But this is a "counsel of perfection" and can seldom be put into actual practice. The common laundry is a necessity of modern conditions of life, and that being so, the only thing remaining to be done is to turn the force of public opinion in the direction of insisting upon such precautions and safeguards as will minimize its inevitable risks. It is, we fear, an obvious deduction from this principle that the cottager laundress ought hardly to be encouraged. She may be a very worthy person, whose industry and independence we should all respect and strongly desire to support. But, in towns at least, where space is narrow and one's next-door neighbor is unknown, there are serious drawbacks to her position. She is too dependent on the goodwill of her customers to be able to enforce a quarantine of infected linen if it be offered to her, and probably too little acquainted with their domestic affairs to know whether there is or is not ground for suspicion. Hence, housekeepers who take a wise view of their responsibilities will prefer to avail themselves of the facilities and guarantees offered by laundries on a larger scale, where the capital employed suffices to provide adequate accommodation and the scale of the operation enables the managers to exercise a judicious supervision over the work which they undertake, and makes it not only possible, but also commercially necessary, for them to decline such as would involve the risk of introducing contagium to their general stock of clothes. Such laundries are at work, and it is, we hope, a question of time only, and that not a long time, for better and more scientific methods to supersede entirely the dangerous laxity of the washerwoman industry.

**THE Medical News** says: "The election of Dr. E. M. Moore, of Rochester, for the presidency of the American Medical Association will be regarded throughout the country with universal satisfaction, both for his personal worth and in recognition of his valuable contributions to practical surgery. It is the crowning honor of a long career devoted to the furtherance of the best interests of the profession and to the material advancement of surgical knowledge. Nashville as the place of meeting has the merit of being central and accessible from all directions."

**MEDICAL SOCIETY NOTES.**—At the one hundred and twenty-third annual meeting of the Medical Society of New Jersey the following officers were elected: President, Dr. B. A. Watson, Jersey City; First Vice-President, Dr. James S. Green, Elizabeth; Second Vice-President, Dr. E. J. Marsh, Patterson; Third Vice-President, Dr. George T. Welch, Keyport; Corresponding Secretary, Dr. William Elmer, Trenton; Recording Secretary, Dr. William Pierson, Orange; Treasurer, Dr. W. W. L. Phillips, Trenton; Standing Committee, Dr. T. J. Smith, Bridgeton; Dr. D. C. English, New Brunswick; and Dr. J. G. Ryerson, Boonton. Essayist for the next meeting, Dr. E. L. B. Godfrey, Camden. The Society will hold its next meeting at Schooley's Mountain.

The Gratiot County, Mich., Medical Society, will hold its annual meeting at Dr. Scott's office, Ithaca, on the 24th inst.

The officers elected by the Toronto (Ont.) Medical Society for the coming year are: President, Dr. A. B. Atherton;

First Vice-President, Dr. B. Spencer; Second Vice-President, Dr. N. A. Powell; Recording Secretary, Dr. G. Acheson; Corresponding Secretary, Dr. W. B. Thistle; Treasurer, Dr. W. J. Greig; Councillors, Drs. J. E. Graham, G. A. Peters, and W. H. B. Aikins.

The Ontario Medical Association have elected the following officers: President, Dr. J. Algernon Temple, Vice-Presidents, First, Dr. Lundy, Preston; Second, Dr. G. Shaw, Hamilton; Third, Dr. K. N. Penwick, Kingston; Fourth, Dr. Hanleip, Waubashene. General Secretary, Dr. D. J. Gibb Wishart, Toronto. Treasurer, Dr. E. J. Barrick, Toronto. Assistant Secretary, Dr. W. P. Caven, Toronto.

**ANENT THE JOURNAL.**—The *British Medical Journal* of the 22d ult., in referring to the Newport meeting says: "Owing in great part to the quiet advocacy of the excellent weekly journal which it owns, the American Medical Association has recently been steadily growing in numbers and in influence."

The *Therapeutic Analyst* says: "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION issued on May 25 an extra edition of 75,000 copies, devoted principally to the interests of the profession in connection with the meeting of the Association at Newport, R. I. This enormous edition was sent out gratuitously to the profession. THE JOURNAL, although always awake to the welfare of the Association, was never more ably edited and judiciously managed than at present."

The *Occidental Medical Times* says: "The Trustees of THE JOURNAL have issued an extra edition of 75,000, which, by good business management, has paid for itself. It contains, amongst other valuable papers, a special article by Dr. Wm. G. Eggleston, on "Our Medical Colleges," that will be read with interest, and should be kept for reference. The full programme of the Association meeting is published, with a description of Newport, handsomely illustrated. THE JOURNAL is steadily gaining in favor with the profession, as the published report of the Trustees will indicate. When it is remembered that any physician belonging to a medical society, in good standing, can, on the payment of \$5, become at once a member of the Association, and receive THE JOURNAL gratis, it is strange that the membership has not increased more rapidly. We hope that this extra edition, which will reach every physician in the United States, will be followed by a large accession."

The *University Medical Magazine* says: "THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 25, 1889, of which an edition of 75,000 copies was issued, was in all respects a most acceptable and praiseworthy enterprise. In addition to the strictly scientific matter, and the satisfactory programme of the Fortieth Annual Meeting of the American Medical Association, the most important contribution is the special article from the pen of Dr. Wm. G. Eggleston, of Chicago, on "Our Medical Colleges." Dr. Eggleston is to be congratulated upon the interesting and carefully gathered statistical information which is found in his report, and especially upon the preparation of the table of American Medical Colleges, together with their matriculation and graduation requirements, obligatory practical and laboratory courses, and other information in regard to the methods of instruction and curriculum."

The *Texas Health Journal* says: "An extra edition of 75,000 copies of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was published on May 25. This was a great enterprise and should be appreciated by the profession of the United States in a substantial manner. The list of Medical Colleges therein contained is of great statistical value."

THE JOURNAL is getting better each year and the medical profession ought to keep the edition standing at 75,000 weekly; this could be done and then there would be about 10,000 physicians without THE JOURNAL."

The *Canadian Practitioner* says: The organ of the

American Medical Association has shown marvellous journalistic enterprise in sending out a special edition of 75,000 copies."

### PAMPHLETS RECEIVED.

The Control and Care of Pauper Inebriates of Towns and Cities. By Lewis D. Mason, M.D., Brooklyn, N. Y. (Reprint.)

On the Value of Frequently Repeated Doses of Arsenic in the Treatment of Bullous Diseases of the Skin, especially in Children. By L. Duncan Bulkley, A.M., M.D., New York. (Reprint.)

On Unusual Methods of Acquiring Syphilis, with Reports of Cases. Same author.

The Animal Suture in Intra-Vaginal Plastic Surgery. By Thomas A. Ashby, M.D., Baltimore, Md. (Reprint.)

Is more Conservatism desirable in the Treatment of the Joint Diseases of Children. By A. B. Judson, M.D., New York.

Fourteenth Annual Announcement of Meharry Medical Department Central Tennessee College, Nashville, Tenn.

Announcement of the National Medical College. Medical Department of the Columbian University, Washington, D. C.

Announcement of the Dental Department of Columbian University, Washington, D. C.

Announcement of the Hospital College of Medicine, Louisville, Ky.

Announcement of the Texas Medical College and Hospital, Galveston, Tex.

Announcement of the Woman's Medical College of the New York Infirmary.

Fourth Annual Report of the New York Cancer Hospital.

Stomach Washing in Infants. By A. Seibert, M.D., New York.

A Contribution to the Study of Muscular Tremor. By Frederick Peterson, M.D., New York. (Reprint.)

### LETTERS RECEIVED.

S. S. White Dental Mfg. Co., Philadelphia; Dr. M. E. Stephens, Albany, N. Y.; Dr. Addison H. Foster, Chicago; Dr. W. H. Begg, Columbus Grove, O.; Dr. James Egan, Racine, Wis.; Dr. Ramsay, St. Cloud, Minn.; Dr. R. T. Bates, New Lebanon, N. Y.; Oneida Spring Co., Utica, N. Y.; Fairchild, Bros. & Foster, New York; Dr. H. M. Lane, Las Paulo, Brazil; Dr. J. W. S. Gouley, New York; Dr. J. W. Powers, Hudson, Ia.; Dr. W. F. Waugh, Philadelphia; Dr. F. S. Dodds, Anna, Ill.; Dr. N. S. Lane, Eyota, Minn.; Dr. J. W. Thompson, St. Paul, Minn.; Dr. C. F. McGahan, Chattanooga, Tenn.; Dr. C. L. Ford, Ann Arbor, Mich.; E. T. Boag, New York; Dr. S. P. Duffield, Detroit, Mich.; Dr. C. A. Harvey, New York; Dr. J. N. Brainerd, Alma, Mich.; Dr. P. O. Hooper, Cincinnati, O.; Dr. F. G. Groner, Big Rapids, Mich.; Dr. Joseph Price, Philadelphia; Dr. J. H. ### Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from June 22, 1889, to July 5, 1889.

Major William H. Forwood, Surgeon, extension of leave of absence on surgeon's certificate of disability granted in S. O. 118, May 23, 1889, from this office, is further extended four months on surgeon's certificate of disability, by direction of the Secretary of War. Par. 14, S. O. 142, A. G. O., Washington, June 20, 1889.

Major J. K. Corson, Surgeon U. S. Army, granted leave of absence for one month, with permission to apply for an extension of one month. Par. 2, S. O. 65, Hdqrs. Dept. of the Columbia.

By direction of the Secretary of War, Major Ezra Woodruff, Surgeon, is relieved from temporary duty at Ft. Monroe, Va., and will report in person to the commanding officer at Ft. Hamilton, N. Y., for duty at that station. Par. 5, S. O. 146, A. G. O., June 25, 1889.

Capt. Walter W. R. Fisher, Asst. Surgeon, extension of leave of absence granted in S. O. 41, Div. of the Pacific, June 12, 1889, is still further extended fifteen days, by direction of the Secretary of War. Par. 8, S. O. 146, A. G. O., Washington, June 25, 1889.

Capt. John Van R. Hoff, Asst. Surgeon U. S. Army, is relieved from duty at Ft. Reno, Ind. Ter., and ordered to Ft. Riley, Kan. Par. 6, S. O. 145, A. G. O., Washington, D. C., June 24, 1889.

Major Dallas Bache, Surgeon U. S. Army, is relieved from duty at Ft. Riley, Kan., and ordered to report to the commanding General, Dept. of the Platte, for duty as Medical Director of that Department. Par. 6, S. O. 145, A. G. O., Washington, D. C., June 24, 1889.

Major J. K. Corson, Surgeon, leave of absence for one month granted by par. 2, S. O. 65, c. s., Dept. of the Columbia, is extended one month. Par. 1, S. O. 45, Hdqrs. Div. of the Pacific, June 24, 1889.

Capt. A. R. Chapin, Asst. Surgeon U. S. Army, granted leave of absence for twenty-five days, to commence on or about July 2, 1889. Par. 6, S. O. 145, Div. of the Atlantic, June 27, 1889.

Capt. R. J. Gibson, Asst. Surgeon U. S. Army, reports arrival July 2, 1889, at Camp Lewis, Fisher's Island, N. Y., in compliance with par. 5, S. O. 133, Div. of the Atlantic, which designated him as medical officer for the encampment (rifle practice) at Fisher's Island, N. Y.

Capt. George T. Beale, Medical Storekeeper, is granted leave of absence for two months, by direction of the Secretary of War. Par. 8, S. O. 148, A. G. O., June 27, 1889.

### Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending June 20, 1889.

Surgeon C. A. Siegfried, detached from the U. S. S. "Quinnebaug" and wait orders.

P. A. Surgeon L. W. Curtis, detached from the U. S. S. "Quinnebaug" and wait orders.

Asst. Surgeon Geo. T. Smith, ordered to the Army and Navy Hospital, Hot Springs, Ark.

## ADDRESSES.

### CONSIDERATIONS CONCERNING SOME EXTERNAL SOURCES OF INFECTION IN THEIR BEARING ON PRE- VENTIVE MEDICINE.

*Being the Address on State Medicine delivered before the American Medical Association, in Newport, on June 28, 1889.*

BY WM. H. WELCH, M.D.,

PROFESSOR OF PATHOLOGY, JOHNS HOPKINS UNIVERSITY,  
BALTIMORE.

No department of medicine has been cultivated in recent years with such zeal and with such fruitful results, as that relating to the causes of infectious diseases. The most important of these results for preventive medicine, and for the welfare of mankind is the knowledge that a large proportion of the causes of sickness and death are removable.

It is evident that efforts to preserve health will be most intelligently and effectually applied when they are based upon an accurate and full knowledge of the agencies which cause disease. Public and private hygiene, however, can not, and fortunately has not, waited for the full light of that day whose dawn has only begun to appear, when we shall have a clear insight into the causation of preventable diseases. Cleanliness and comfort demand that means shall be taken to render pure the ground on which we live, the air which we breathe, and the water and food with which we are supplied, and we must meet these needs without waiting to learn just what relation infectious agents bear to the earth, air, water and food.

It is a fortunate circumstance that modern sanitation has been controlled so largely by the belief in the dependence of endemic and epidemic diseases upon organic impurities in the soil and in the water. Incomplete and even erroneous in many respects, as are the views which have prevailed concerning the origin and spread of epidemic diseases by the decomposition of organic substances, the sanitary measures which have been directed toward the removal of filth have achieved great conquests in limiting the development and extension of many infectious diseases.

The benefits which one Commonwealth of this country has derived from the intelligent employment of public sanitary measures were clearly and forcibly presented before this Association last year by Dr. Walcott in his admirable Address on State Medicine.

While nothing should be said, or need be said, to lessen the importance of cleanliness for public health, it is important to bear in mind, that hygienic cleanliness and æsthetic cleanliness are not identical. In water which meets the most severe chemical tests of purity typhoid bacilli have been found. On the other hand, the air in the Berlin sewers, which certainly does not meet the most modest demands of æsthetic cleanliness, has been found to be nearly or quite free from bacteria.

It needs only to be stated to be generally admitted that the scientific basis of preventive medicine must be the accurate knowledge of the causative agents of preventable diseases, a knowledge which can be derived only from a careful study of all of the properties of these agents, the modes of their reception and of their elimination by the body, the circumstances which favor, and those which retard or prevent their development and spread, their behavior in the various substances which surround us, or which we take into our bodies and the sources of infection, not only those which laboratory experiments show to be possible, but those which are actually operative.

So long as we were unacquainted with the living organisms causing infection, the means at our disposal for studying the etiology of infectious diseases were limited to the observation of all of the circumstances which we could determine regarding the origin and spread of these diseases. We could only infer what might be the properties of the infectious agents from the study of phenomena often obscure and difficult of interpretation. Chiefly by this method of investigation the science of epidemiology has been built up. It has established facts and laws no less of practical than of scientific importance. But it has left unsolved many problems, and has filled gaps with speculations. Admitted epidemiological facts are often open to various interpretations.

We are evidently at a great advantage when we can study the epidemiological facts with a knowledge of the substances which actually cause in-

fection, and this we are now enabled to do for a limited number of the infectious diseases. This new method of research, which thus far has been mainly bacteriological, has aided us not so much by simplifying the problems of etiology, which still remain complicated enough, as by affording greater accuracy to the results.

It is my aim in this address to consider some results of the modern studies of pathogenic microorganisms in their bearing upon preventive medicine, more particularly upon the sources of infection. It is, of course, impossible within the limits of the address, to attempt a complete survey of this important field. Time will permit the presentation of only some of the salient points.

Infectious diseases are those which are caused by the multiplication within the body of pathogenic microorganisms.

It has always been recognized that some infectious diseases, such as the exanthematous fevers, are conveyed directly from the sick to the healthy. It is not disputed that in these, evidently contagious diseases, the infectious germ is discharged from the body in a state capable at once of giving rise to infection.

In a second group of infectious diseases, of which malaria is the type, the infected individual neither transmits the disease to another person, nor, so far as we know, is capable of infecting a locality. Here there is a reason to believe that the infectious germ is not thrown off in a living state from the body, but is destroyed within the body. In this group the origin of infection under natural conditions is always outside of the body.

In a third group there is still dispute whether the disease can be transmitted directly from person to person, but all are agreed that the infected individual can infect a locality. It is especially fortunate that the bacteria which cause cholera and typhoid fever, the two most important representatives of this group of so-called miasmatic-contagious diseases, have been discovered and isolated in pure culture. These are the diseases about whose origin and epidemic extension there has been the greatest controversy. They, above all other diseases, have given the impulse to public sanitation during the last half century. The degree of success with which their extension in a community is prevented is an important gauge of the excellence of the local sanitary arrangements. A clear comprehension of the origin and spread of these diseases signifies the solution of many of the most vexed and important problems of epidemiology and of State hygiene.

It is difficult to understand how those who accept the discovery that the bacteria causing typhoid fever and cholera, have been found and cultivated from the stools of patients affected with these diseases, can doubt that these patients are possible sources of contagion, or can entertain the

view once so widely prevalent that the infectious germs of these diseases are discharged from the body in a condition incapable of producing immediate infection. In an address delivered on another occasion, I have endeavored to present the consideration which reconcile the comparative infrequency of direct contagion for these diseases, with the belief in the elimination of the causative germs in an active state from the body, and have there pointed out several well known factors which determine the frequency of conveyance of an infectious disease by contagion. There are reasons, some of them very obvious, why diseases in which the infectious substances are operative only when received into the digestive tract, and are discharged usually only with the feces, are less likely to be transmitted by immediate contagion than those diseases in which the virus is thrown off from the skin on epidermal scales.

But the field of operation of direct contagion for these so-called miasmatic-contagious diseases is at most a restricted one, and the chief sources of infection are outside of the body from which primarily the infectious germs may have been derived. It is to these external sources of infection, which are of such importance in public hygiene, that I wish especially to direct attention.

A full comprehension of the sources of infection is, of course, to be obtained only by a detailed study of the etiology of the individual infectious diseases, but this is, of course, impossible within the limits of an address. It may, however, be useful to present some of the facts which have a general bearing upon the subject. Let us consider, then, from the point of view of modern bacteriological studies, what rôle in harboring or transporting infectious agents, may be played by those substances or media with which we necessarily come into intimate contact, such as the air, the ground, the water and our food.

It is universally admitted that many infectious agents may be transported by the air, but the extent of danger from this source has often been exaggerated. It is a popular error to suppose that most of the minute particles of dust in the air either are or contain living organisms. The methods for determining the number, and kind of bacteria and fungi in the air, are now fairly satisfactory, although by no means perfect. These have shown that while the number of living bacteria and fungi in the atmosphere, in and around human habitations cannot be considered small, still it is greatly inferior to that in the ground or in most waters. Unlike fungus spores, bacteria do not seem to occur to any extent in the air as single detached particles, which would then necessarily be extremely minute, but rather in clumps or attached to particles of dust of relatively large size. As a result in a perfectly quiet atmosphere, these comparatively heavy particles which contain bacteria, rapidly settle to the ground or upon

underlying objects, and are easily filtered out by passing the air through porous substances, such as cotton-wool or sand. Rain washes down a large number of bacteria from the air. That the air bacteria are derived from the ground or objects upon it is shown by their total absence, as a rule, from sea air at a distance from land, this distance naturally varying with the direction and strength of the wind.

A fact of capital importance in understanding the relations of bacteria to the air, and one of great significance for preventive medicine, is the impossibility of currents of air detaching bacteria from moist surfaces. Substances containing pathogenic bacteria, as, for instance, sputum containing tubercle bacilli or excreta holding typhoid bacilli, can not, therefore, infect the air unless these substances first become dry and converted into a fine powder. We are able to understand why the expired breath is free from bacteria and cannot convey infection, except as little particles may be mechanically detached by acts of coughing, sneezing or hawking. Those bacteria, the vitality of which is rapidly destroyed by complete desiccation, such as those of Asiatic cholera, evidently are not likely to be transported as infectious agents by the air, if we except such occasional occurrences as their conveyance for a short distance in spray.

The only pathogenic bacteria which hitherto have been found in the air, are the pus organisms, including the streptococci, found by Prudden in a series of cases of diphtheria, and tubercle bacilli, but no far-reaching conclusions can be drawn from the failure to find other infectious organisms when we consider the imperfection of our methods, and the small number of observations directed to this point. The evidence in other ways is conclusive that many infectious agents—and here the malarial germ should be prominently mentioned—can be, and often are, conveyed by the air. While we are inclined to restrict within narrower limits than has been customary the danger of infection through the air, we must recognize that this still remains an important source of infection for many diseases. All those, however, who have worked practically with the cultivation of microorganisms, have come to regard contact with infected substances as more dangerous than exposure to the air, and the same lesson may be learned from the methods which modern surgeons have found best adapted to prevent the infection of wounds with the cosmopolitan bacteria, which cause suppuration.

We are not, of course, to suppose that infectious germs floating in the form of dust in the atmosphere are dangerous, only from the possibility of our drawing them in with the breath. Such germs may be deposited on substances with which we readily come into contact, or they may fall on articles of food where they may find conditions

suitable for their reproduction, which cannot occur when they are suspended in the air in consequence of the lack of moisture.

From the facts which have been mentioned concerning the relations of bacteria to the air, what points of view present themselves to guide us in preventing infection through this channel? Surely something more than that this purpose is accomplished simply by abolishing foul odors.

Certain indications are so plain as to need only to be mentioned in this connection, such as the disinfection and removal, as far as possible, of all infected substances, an indication which applies equally to all channels of infection, and which it is much easier to mention than it is to describe how it shall be realized. But there are two indications which apply especially to the prevention of the transportation of disease germs by the air. One is the necessity of guarding, so far as practicable, against the desiccation, when exposed to the air, of substances which contain infectious germs not destroyed by drying, and another is free ventilation.

For no disease is the importance of the first of these indications so evident and so well established as for tuberculosis, the most devastating of all infectious diseases. Against this disease, formidable as it may seem to cope with it, the courageous crusade of preventive medicine has begun, and is destined to continue.

It is now generally recognized that the principal, although not the sole, sources of tuberculous infection are the sputum of individuals affected with pulmonary tuberculosis and the milk of tuberculous cows. Cornet, who has made a laborious and most instructive experimental study of the modes and dangers of infection from tuberculous sputum, has also elaborated the practical measures which should be adopted to diminish or annihilate these dangers. These measures have been so recently and so widely published in medical journals, and so clearly presented before a Section of this Association, that I mention them only to call the attention of practitioners of medicine to their importance, and to emphasize the fact that they are based chiefly upon the principle that infectious substances of such nature as tuberculous sputum should not be allowed to become dry and converted into dust when exposed to the air.

By means of free ventilation, disease-producing microorganisms which may be present in the air of rooms, are carried away and distributed so far apart that the chance of infection from this source is removed or reduced to a minimum. It is a well-established clinical observation that the distance through which the specific microbes of such diseases as small-pox or scarlatina are likely to be carried from the patient by the air, in such concentration as to cause infection, is small, usually not more than a few feet, but increases by

crowding of patients and absence of free ventilation. The well-known experiences in the prophylaxis and treatment of typhus fever are a forcible illustration of the value of free ventilation.

It is, of course, not to be understood that by ventilation we accomplish the disinfection of a house or apartment. Ventilation is only an adjunct of such disinfection which, as already mentioned, is of first importance. Time will not permit, nor is it in the plan of this address, to discuss the details of such questions as house disinfection, but I may be permitted to say that the methods for disinfecting apartments have been worked out on a satisfactory experimental basis, and should be known, at least, by all public health officers. Whether it be pertinent to this occasion or not, I cannot forbear to add my protest to that of others against placing reliance upon any method hitherto employed of disinfecting houses or apartments by fumigation. And I would, furthermore, call attention to the lack in most cities of this country of public disinfecting establishments, such as are in use with excellent results in many cities of Europe, and which are indispensable for the thorough and convenient disinfection of clothing, bedding, carpets, curtains, etc.

After this short digression let us pass from the consideration of the air as a carrier of infection to another important external source of infection, namely, the ground. That the prevalence of many infectious diseases depends upon conditions pertaining to the soil cannot be questioned, but the nature and the extent of this influence have been and are the subjects of lively discussion. The epidemiological school led by Pettenkofer, assigns as is well-known, to the ground the chief, and even a specific and indispensable influence in the spread of many epidemic diseases, particularly cholera and typhoid fever. The statistics, studies and speculations of epidemiologists which have related to this subject, probably surpass in number and extent those concerning any other epidemiological factor. The exclusive ground hypothesis has become an ingenious and carefully elaborated doctrine with those who believe that such diseases as cholera and typhoid fever can never be transmitted by contagion. These authorities cling to this doctrine with a tenacity which indicates that on it depends the survival of the exclusively localistic dogma for these diseases.

To all who have not held aloof from modern bacteriological investigations, it must be clear that views which have widely prevailed concerning the relations of many infectious germs to the soil require revision. The question is still a difficult and perplexing one, but on some hitherto obscure or misunderstood points these investigations have shed light, and from the same source we may expect further important contributions to a comprehension of the relations of the ground to the development of infectious diseases.

The ground, unlike the air, is the resting or the breeding place of a vast number of species of microorganisms, including some which are pathogenic. Instead of a few bacteria or fungi in a liter as with the air, we find in most specimens of earth thousands, and often hundreds of thousands of microorganisms in a cubic centimeter. Fraenkel found the virgin soil almost as rich in bacteria and fungi as that around human habitations.

This vast richness in microorganisms belongs, however, only to the superficial layers of the earth. Where the ground has not been greatly disturbed by human hands, there is, as a rule, about three to five feet below the surface an abrupt diminution in the number of living organisms, and at the depth where the sub-soil water usually lies, bacteria and fungi have nearly or entirely disappeared. Fraenkel, who first observed this sudden diminution in the number of microorganisms at a certain level beneath the surface, explains this singular fact by the formation at this level of that sticky accumulation of fine particles consisting largely of bacteria which forms the efficient layer in large sand filters for water. Of course the number of bacteria, and the depth to which they penetrate, will vary somewhat with the character, especially the porosity of the soil and its treatment, but the important fact that all, or nearly all of the bacteria and fungi are retained in the ground above the level of the sub-soil water, will doubtless hold true for most situations.

The conditions are not favorable for the multiplication of bacteria in the depth of the ground, as is shown by the fact that in specimens of earth brought to the surface from a depth of a few feet, the bacteria which are at first present, rapidly multiply. What all of the conditions are which prevent the reproduction of bacteria in the deep soil has not been ascertained, but the fact necessitates similar precautions in the bacteriological examination of the soil as in that of water.

We have but meagre information as to the kinds of bacteria present in the ground in comparison with their vast number. Many of those which have been isolated and studied in pure culture possess but little interest for us so far as we know. To some of the microorganisms in the soil appears to be assigned the rôle of reducing or of oxidizing highly organized substances to the simple forms required for the nutrition of plants. We are in the habit of considering so much the injurious bacteria that it is pleasant to contemplate this beneficent function, so essential to the preservation of life on this globe.

Among the pathogenic bacteria which have their natural home in the soil the most widely distributed are the bacilli of malignant œdema and those of tetanus. I have found some garden earth in Baltimore extremely rich in tetanus bacilli, so that the inoculation of animals in the

laboratory with small bits of this earth rarely fails to produce tetanus. In infected localities the anthrax bacillus and in two instances the typhoid bacillus, so far as it was possible to identify it, have been discovered in the earth. There is reason to believe that other germs infectious to human beings may have their abiding place in the ground; certainly no one doubts that the malarial germ lives there. As the malarial germ has been shown to be an organism entirely different from the bacteria and the fungi, we cannot apply directly to its behavior in the soil and its transportation by the air, facts which have been ascertained only for the latter species of microorganisms, and the same precautions must be observed for other diseases with whose agents of infection we are not acquainted, as, for instance, yellow fever.

In view of the facility with which infectious germs derived from human beings or animals may gain access to the soil, it becomes a matter of great importance to determine how far such germs find in the soil conditions favorable for their preservation or their growth. We have, as is well known, a number of epidemiological observations bearing upon this subject, but with few exceptions these can be variously interpreted, and it is not my purpose to discuss them. The more exact bacteriological methods can, of course, be applied only to the comparatively small number of infectious diseases the causative germs of which have been isolated and cultivated, and these methods hitherto have been applied to this question only imperfectly. We cannot regard the soil as a definite and unvarying substance in its chemical, physical and biological properties. What has been found true of one kind of soil may not be so of another. Moreover, we cannot in our experiments bring together all of the conditions in nature which may have a bearing on the behavior of specific microorganisms in the soil. We must, therefore, be cautious in coming to positive conclusions on this point on the basis of experiments, especially those with negative result. With these cautions kept constantly in mind the question, however, is one eminently open to experimental study.

The experiments which have thus far been made to determine the behavior of infectious microorganisms in the ground have related especially to the bacilli of anthrax, of typhoid fever and of cholera, and, fortunately, these are the diseases about whose relations to the ground there has been the most discussion, and concerning which we are most eager to acquire definite information.

As regards anthrax bacilli, it has been determined that in ordinary garden or field earth they do not multiply, but in earth contaminated by blood, urine or feces their reproduction can occur. They can grow on various vegetable substrata. There is no reason to doubt, therefore, that the anthrax bacilli can find in or on the ground suitable conditions for their multiplication, although

such conditions are not everywhere present. For durable infection of the soil with anthrax bacilli it is, however, more important that these bacilli should find there suitable conditions for the formation of spores, than that they should be able simply to multiply. The vegetable forms of anthrax bacilli would not, as a rule, be able to survive for any great length of time the hostile influences which they are likely to encounter in the ground, such as insufficient or exhausted nutriment, absence of sufficient moisture and the attacks of saprophytic organisms. On the other hand, against these injurious influences the anthrax spores have great resistance. In the superficial layers of the ground the anthrax bacilli may often find those conditions of moisture, of temperature, of oxygen supply and of insufficient food which we know are most favorable for the development of their spores; indeed, Soyka has shown that the ground presents often these conditions better than our culture media. A circumstance discovered by Feltz, which, however, needs confirmation, is, if true, of not little significance. He finds that anthrax bacilli may undergo a progressive diminution in virulence in the soil. If this should be true likewise of other infectious microorganisms, we should be able to account in some instances for the variable degree of virulence which clinical observation indicates that certain agents of infection acquire. So far as anthrax bacilli are concerned, we may conclude, therefore, that the ground occasionally offers suitable conditions for their reproduction, but what is of greater importance, it offers especially favorable conditions for their long-continued preservation in the form of spores. I must forego here the further consideration of the special circumstances inherent in the soil which control the origin and spread of epidemics of anthrax in cattle, although many interesting investigations have been directed to this subject.

Of greater interest to physicians is the behavior of typhoid and of cholera bacteria in the ground. As has already been intimated, the ground is regarded by Pettenkofer and his school as the principal breeding-place of these microorganisms outside of the body. This view, however, is not supported by bacteriological investigations. Inasmuch as the cholera and typhoid bacilli may multiply on various vegetable substrata and substances derived from animals at temperatures often present in the ground, it is evident that here and there conditions may be present for their growth in the ground, but this growth is likely to be soon interrupted by the invasion of ordinary saprophytic organisms and other harmful influences. The typhoid bacilli are more hardy in resisting these invaders than are the cholera bacteria, which easily succumb, but even for the former, so far as our present knowledge extends, the ground can rarely serve as a favorable breeding-place.

It is not, however, necessary that these organisms should multiply in order to infect for a considerable time the ground; it is sufficient if their vitality is preserved. As to this latter point, the reports of different investigators are not altogether concordant. Such excellent observers as Koch, Kitasato and Uffelmann found that the cholera bacteria, when added to feces or a mixture of feces and urine, rapidly diminished in number and, at the end of three or four days at the most, had wholly disappeared. In a mixture of the intestinal contents from a cholera corpse with earth and water Koch found numerous cholera bacteria at the end of three days, but none at the end of five days. On the other hand, Gruber reports the detection of cholera bacteria in cholera dejecta fifteen days old. The weight of bacteriological evidence, therefore, is opposed to the supposition that the bacteria of Asiatic cholera preserve their vitality for any considerable time in the ground or in the excreta.

With respect to the bacilli which cause typhoid fever, it has been shown by Uffelmann that these may live in feces, mixture of feces and urine, and mixture of garden earth, feces and urine for at least four and five months, and doubtless longer, although they may die at the end of a shorter period. He also finds that, under these apparently unfavorable conditions, some multiplication of the bacilli may occur, although not to any considerable extent. Grancher and Deschamps found that typhoid bacilli may live in the soil for at least five months and a half. Unlike the cholera bacteria, therefore, the typhoid bacilli may exist for months at least in the ground and in fecal matter, holding their own against the growth of multitudes of saprophytes. This difference in the behavior of cholera and of typhoid germs is in harmony with clinical experience.

As regards other infectious bacteria than those which have been considered I shall only mention that tubercle bacilli, although incapable of multiplication under the ordinary conditions of nature outside of the body, may preserve their vitality for a long period in the ground, on account of their resistant character; and furthermore, that the pyogenic cocci, on account of their considerably resistant nature and their modest demands in the way of nutriment, can be preserved and sometimes, probably, grow in the ground. Indeed, the staphylococcus pyogenes aureus has been found in the earth by Lübbert.

The conclusion which we may draw from the observations mentioned is that, in general, the soil is not a good breeding-place for most of the infectious bacteria with which we are acquainted, but that it can retain for a long time with unimpaired vitality those which produce spores or which offer considerable resistance to injurious agencies, such as anthrax bacilli, typhoid bacilli, tubercle bacilli and the pyogenic cocci.

In order to become infected with bacteria in or on the ground these bacteria must in some way be introduced into the body; and we must, therefore, now attempt to determine how bacteria may be transported to us from the ground. So various and intricate are the possibilities for this transportation that it is hopeless to attempt to specify them all.

There occurs to us first the possibility of the conveyance of infectious microorganisms from the soil by means of currents of air, a mode of carrying infection which has already been considered. Here I shall only repeat that the wind can remove bacteria from the ground only when the surface is dry and presents particles of dust, and that the sole, and perhaps the chief, danger is not that we may inhale the infected dust.

Manifold are the ways in which we may be brought into contact with infectious bacteria in the ground, either directly or by means of vegetables to which particles of earth are attached, by the intervention of domestic animals, by the medium of flies or other insects, and in a variety of other ways, more or less apparent.

An important, doubtless for some diseases the most important, medium of transportation of bacteria from an infected soil is the water which we drink or use for domestic purposes. From what has been said it is evidently not the subsoil water which is dangerous, for infectious like other bacteria cannot generally reach this in a living state, but the danger is from the surface water and from that which trickles through the upper layers of the ground, as well as from that which escapes from defective drains, gutters, cesspools, privy vaults and wrongly constructed sewers or improper disposal of sewage. I shall have something to say presently of water as a source of infection and shall not further elaborate here the dangers of infection of drinking-water through contaminated soil, dangers which, especially as regards typhoid fever, are widely appreciated in this country, even if often imperfectly counteracted.

A point which has been much discussed, and one of interest, is whether bacteria which are in the depths of the ground can come to the surface. Two agencies especially have been considered by some as capable of transporting bacteria from the depth to the surface. One is ascending currents of air in the ground and the other is the capillarity of fluids in the minute pores of the ground. The first of these suspected agencies must be unquestionably rejected in view of the fact that even a few inches of sand is sufficient to filter all of the bacteria out of the air, even when it is in much more rapid motion than can occur within the ground. Moreover, that degree of dryness which is essential for the detachment of bacteria by air-currents is not likely to be present much below the surface of the ground. The experiments

which have been made to determine to what extent bacteria may be carried upward by the capillarity of fluids in the ground have not yielded harmonious results, but the weight of evidence is opposed to the belief that this is a factor of any considerable importance for this purpose.

From what has been said concerning the growth of pathogenic bacteria in the soil we shall not be inclined to attribute to the multiplication and the motility of these organisms much influence in changing their place in the ground.

The somewhat sensational rôle assigned by Pasteur to earth worms of bringing bacteria to the surface cannot be wholly ignored and has received support from observations of Bollinger regarding anthrax, but it is questionable whether much importance is to be attached to this agency.

Regarding the depth to which typhoid bacilli may penetrate in the soil, the experiments of Grancher and Deschamps show that at the end of five weeks they may reach a depth of 16 to 20 inches below the surface. As Hoffmann has demonstrated the extraordinary slowness with which fluids and fine particles penetrate the soil, it is probable that in the course of time a greater depth than this may be reached. Indeed, Macé claims to have found in the neighborhood of a wall, suspected of infection, typhoid bacilli, together with ordinary intestinal bacteria, at a depth of at least  $6\frac{1}{2}$  feet below the surface. There are a number of instances recorded in which there is good reason to believe that turning up the soil and cleaning out privies or dung-heaps in which typhoid stools have been thrown, have given rise to typhoid fever, even after the infectious excreta have remained there a year and more.

It cannot be said that bacteriological investigations have as yet shed much light upon a factor which plays a great rôle in epidemiology, namely, predisposition to infection from the ground, according to locality and time, and this deficiency receives constant and vehement emphasis from the localistic school of epidemiologists. We can, however, readily understand that varying conditions, such as temperature, moisture, porosity, quality of soil may exert a controlling influence in determining the behavior of infectious germs in the soil and the facility of their transportation to human beings or animals. As regards that much-discussed question, the significance of variations in the height of the subsoil water, in relation to the prevalence of certain epidemic diseases, particularly cholera and typhoid fever, we now know that this cannot depend upon the presence of bacteria in the subsoil water itself or in the capillary layers immediately above it. It has been plausibly suggested that with the sinking of the subsoil water fluids from infected cesspools, privy vaults, and other localities may more readily be drawn into wells or other sources of water-

supply, and that by the same cause the surface of the ground becomes dry, so that dust particles may be lifted by the wind. Other more or less plausible explanations have also been offered, but it must be confessed that our positive information on this point is meagre. There can, however, be little doubt that this significance of the variations in subsoil water is apparent only for certain localities and has been considerably exaggerated and often misunderstood. It is not, however, pertinent to my theme to discuss this or other purely epidemiological observations concerning the relations of the ground to the spread of epidemic diseases, interesting and important as are many of these observations.

Before leaving the subject of the ground as a source of infection, permit me to indicate briefly some conclusions which may be drawn from what has been said as to the principles which should guide us in preventing infection directly or indirectly from the ground.

First in importance is to keep infectious substances, so far as possible, from the ground. This implies the early disinfection or destruction of such substances as typhoid and cholera excreta and tuberculous sputum.

Second. The ground should be rendered, so far as practicable, unsuitable for the continued existence of infectious germs. This, at least for some diseases, is accomplished by a proper system of drainage, which, moreover, for other reasons possesses hygienic importance.

Third. Means should be provided to prevent waste products from getting into the ground around human habitations or from gaining access to water used for drinking or domestic purposes. In cities this can be accomplished only by a properly constructed system of sewers. The system of storing waste products in cesspools, whence they are to be occasionally removed cannot be approved on hygienic grounds. There are conditions in which the disposal of waste products in deep wells only used for this purpose and whence these products can filter into the deep layers of the ground may be permissible, but this can never be considered an ideal method of getting rid of excrementitious substances and is wholly wrong in regions where wells are used for drinking water. But I am trespassing with these remarks upon a province which does not belong to me, but rather to practical sanitarians and engineers. I shall only add that the advantage gained by preventing organic waste from soaking into the ground is not so much that the ground is thereby rendered better adapted for the existence of infectious microorganisms, but is due rather to the fact that this waste is likely to contain infectious germs.

Finally, in cities good pavements, absence of unnecessary disturbance of the soil, cleanliness of the streets and laying of the dust by sprinkling are not only conducive to comfort but are some-

times hygienically important in preventing infection from the ground and dust.

In passing from the consideration of the ground to that of water one feels that he now has to do with a possible source of infection against which in this country and in England he is at liberty to make any accusation he chooses without fear of contradiction. There is reason to believe that such accusation has been repeatedly made without any proof of misdemeanor on the part of the water. It is not, therefore, with any desire to awaken further the medical or public conscience that I wish to say a few words concerning the behavior of bacteria in water and the dangers of infection from this source. That such dangers are very real must be apparent when we consider the universal employment of water and its exposure to contamination from all kinds of sources.

Ordinary water, as is well known, contains bacteria in large number. Not a few species of bacteria can multiply rapidly and to a large amount even in distilled water. These are so-called water-bacteria, and like most of the microorganisms found in ordinary drinking water are perfectly harmless saprophytes. What we wish to know is, how pathogenic microorganisms conduct themselves in water. Can they grow or be preserved for any length of time in a living condition in water? As regards the multiplication of pathogenic bacteria in water the results of different experimenters do not altogether agree. Whereas Bolton failed to find any growth, but rather a progressive diminution in number of pathogenic bacteria planted in sterilized water, Wolffhügel and Riedel observed a limited reproduction of such bacteria, including those of typhoid fever and of cholera. This difference is due probably to the methods of experimentation employed. According to Kraus, these latter bacteria diminish rapidly in number in unsterilized spring or well water kept at a low temperature. These experiments indicate that water, even when contaminated with more organic impurities than are likely ever to be present in drinking water, is not a favorable breeding place for pathogenic bacteria. Still it is to be remembered that these laboratory experiments do not reproduce exactly all of the conditions in nature, and it may happen that in some nook or cranny or vegetable deposit at the side of a well or stream some pathogenic bacteria may find suitable conditions for their multiplication.

But, as has been repeatedly emphasized in this address, it is not necessary that pathogenic bacteria should actually multiply in a medium in order to render it infectious. It is sufficient if their life and virulence are not destroyed in a very short time. As to this important point, Bolton found that in sterilized water typhoid bacilli may preserve their vitality for over three months and cholera bacteria for eight to fourteen days, while

Wolffhügel and Riedel preserved the latter in water for about eighty days. Under natural conditions, however, these organisms are exposed to the overgrowth of the water bacteria, so that Kraus found in unsterilized water kept at a temperature of  $10.5^{\circ}\text{C}$ . the typhoid bacilli no longer demonstrable after seven days, and the cholera bacteria after two days. The conditions in Kraus's experiments were as unfavorable as possible for the continued existence of these pathogenic bacteria, more unfavorable than those often present at the season of prevalence of cholera and typhoid fever, nevertheless I do not see that they justify the conclusions of Kraus as to the slight probability of drinking water ever conveying infection with the germs of typhoid fever and of cholera. To render such a conclusion probable it would be necessary to demonstrate a much shorter preservation than even Kraus himself found. In judging this question it should not be overlooked that infection of drinking water with the typhoid or the cholera germs is not so often the result of throwing typhoid or cholera stools directly into the source of water-supply as it is the consequence of leaky drains, cesspools, privy-vaults or infected soil, so that there may be continued or repeated accessions of infected material to the water.

In view of the facts presented, there is no sufficient reason, therefore, from a bacteriological point of view, of rejecting the transmissibility of typhoid fever and cholera by the medium of drinking water. This conclusion seems irresistible when we call to mind that Koch once found the cholera bacteria in large number in the water of a tank in India, and that the typhoid bacilli have been repeatedly found in drinking water of localities where typhoid fever existed. Nor do I see how it is possible to interpret certain epidemiological facts in any other way than by assuming that these diseases can be contracted from infected drinking water, although I know that there are still high authorities who obstinately refuse to accept this interpretation of the facts.

In this connection it may be mentioned that pathogenic bacteria may preserve their vitality longer in ice than in unsterilized drinking water. Thus Prudden found typhoid bacilli still alive which had been contained in ice 103 days.

When we come to consider the ways in which water may become infected with pathogenic microorganisms we recognize at once a distinction in this respect between surface water and subsoil water. Whereas the subsoil water may be regarded under ordinary circumstances and in most places as germ-free, the surface water, such as that in rivers and streams, is exposed to all manner of infection from the ground, the air, and the direct admission of waste substances. Unfortunately in the ordinary way of obtaining subsoil water for drinking purposes by means of dug wells this distinction is obliterated, for the water

which enters these wells free from bacteria is converted into a surface water often exposed, by the situation of the well, to more dangerous contamination than other surface waters used for drinking purposes.

Now let us turn our attention, as we have done with other sources of infection, to a brief outline of certain general principles which may help us in avoiding infection from the water.

We shall in the first place avoid so far as possible the use of water suspected of infection, especially with the germs of such diseases as typhoid fever and cholera. When it is necessary to use this suspected water it should be boiled.

As regards the vital question of water-supply, it may be stated as a general principle that no hygienic guarantee can be given for the purity of surface water which has not been subjected to a proper system of filtration, or for the purity of spring or well water fed from the subsoil, unless such water is protected from the possibility of infection through the upper layers of the soil or from the air. This is not saying that water which meets certain chemical and biological tests and which is so situated that the opportunities for its contamination appear to be absent or reduced to a minimum is not admissible for the supply of drinking water, but the possibility of infection can be removed only by the fulfillment of the conditions just named, and upon these conditions the hygienic purist will always insist.

Unfortunately we have at present no domestic filters which are satisfactory, and most of those in common use are worse than none, as they soon furnish a filtrate richer in bacteria than the original water. The only effective method of water-filtration for the general supply is by means of large sand filters, such as are in use with excellent results in Berlin and some other cities. These require skilled attention. I cannot on this occasion discuss the construction or working of these filters, but would refer those who are interested to the full and careful investigation of the Berlin filters by Wolffhügel and by Plagge and Proskauer.

What is accomplished by these artificial sand filters is accomplished under natural conditions, also by the ground, which furnishes a subsoil water free from microorganisms, and to obtain pure water we have only to devise means by which this subsoil water may be secured without the chance of contamination. Just as the water which has passed through the sand filters is collected in suitable reservoirs and is distributed in pipes, which do not admit contamination from without, so by means of properly constructed artesian or driven wells we may secure the naturally filtered subsoil water with the same freedom from the chances of infection.

It is well to bear in mind that no biological or chemical tests of water can replace those measures

which have been mentioned as necessary to secure purity of water-supply. These tests are of value only when applied with proper precautions and with due consideration of the special circumstances of each case for which they are employed. There has been much profitless discussion as to whether greater significance is to be attached to the chemical or to the bacteriological examination of water. Each has its own special field of application and in this the one cannot replace the other method. The bacteriological examination has for hygienic purposes the advantage that it may enable us to detect the specific agents of infection in the form of microorganisms, as has already been done for cholera bacteria and typhoid bacilli, but this is a comparatively rare result and does not at present afford a wide field of application for this method. The significance of the bacteriological test is to be based more frequently upon the fact that it concerns itself with the same class of microorganisms to which some of the recognized and doubtless many of the undiscovered infectious agents belong and from the behavior of which in some respects conclusions can be drawn as to the behavior of the pathogenic organisms. Thus the bacteriological test is the only one which enables us to judge correctly of the efficacy of those methods of filtration of surface water and of construction of wells which insure purity of water-supply. The points of view from which we can estimate correctly according to our present knowledge the relative merits and fields of application of the chemical and of the bacteriological methods of water examination have been clearly indicated by Plagge and Proskauer, and by Wolffhügel. The theme is one beyond the limits or the scope of this discourse and I have referred to it chiefly to emphasize the fact that we cannot rely upon chemical or bacteriological tests of water to the exclusion of those protective measures which have been mentioned, although I do not intend to imply that each of these tests when properly employed does not afford important information and is not of great value in many cases.

I have already taxed so largely your time and patience that I must pass over with brief mention the food as a source of infection. Unlike those external sources of infection which we have hitherto considered, many articles of food afford an excellent nutritive medium for the growth of a number of species of pathogenic microorganisms, and in many instances this growth may be abundant without appreciable change in the appearance or taste of the food.

When we consider in how large degree the certainty and the severity of infection with many kinds of pathogenic microorganisms depend upon the number of such organisms received into the body, we can appreciate that the danger of infection from food which contains a mass of growing

pathogenic bacteria may be much greater than that resulting from the reception of infected water or aid, media in which infectious organisms are rarely present in other than a very dilute condition. The entrance into the body of a single infectious bacterium with the inspired air is, at least in the case of many diseases, not likely to cause infection, but let this bacterium fall upon some article of food, as for instance upon milk, where it can multiply in a short time at a favorable temperature many thousand-fold and evidently the chances of infection become vastly increased.

Among the various agencies by which infectious organisms may gain access to the food may be mentioned the deposition of dust conveyed by the air, earth adhering to vegetables, water used in mixing with or in the preparation of food, in cleansing dishes, clothes, etc., and contact in manifold other ways with infected substances.

Fortunately a very large part of our food is sterilized in the process of cooking shortly before it is partaken, so that the dangers of infection from this source is greatly diminished and comes into consideration only for uncooked or partly cooked food and for food which, although it may have been thoroughly sterilized by heat, is allowed to stand a considerable time before it is used. Milk, in consequence of its extensive employment in an unsterilized state and of the excellent nutritive conditions which it presents to many pathogenic bacteria, should be emphasized as especially liable to convey certain kinds of infection; a fact supported not less by bacteriological than by clinical observations. Hesse found that also a large number of ordinary articles of food prepared in the kitchen in the usual way for the table and then sterilized afford a good medium for the growth and preservation of typhoid and cholera bacteria, frequently without appreciable change in the appearance of food.

Upon solid articles of food bacteria may multiply in separate colonies, so that it may readily happen that only one or two of those who partake of the food eat the infected part, whereas with infected liquids, such as milk, the infection is more likely to be transmitted to a larger number of those who are exposed.

In another important particular the food differs from the other sources of infection which we have considered. Not only the growth of infectious bacteria, but also that of bacteria incapable of multiplication within the body may give rise in milk and other kinds of food to various ptomaines, products of fermentation and other injurious substances which when ingested are likely to cause more or less severe intoxication or to render the alimentary tract more susceptible to the invasion and multiplication of genuinely infectious organisms.

It is plain that the liability to infection from food will vary according to locality and season.

In some places and among some races the proportions of uncooked food used is much greater than in other places and among other races. In general in summer and in autumn the quantity of fruit and food ingested in the raw state is greater than at other seasons, and during the summer and autumn there is also greater danger from the transportation of disease germs from the ground in the form of dust, and the amount of liquids imbibed is greater. The elements of predisposition according to place and time upon which epidemiologists are so fond of laying stress are not therefore absent from the source of infection now under consideration.

I have thus far spoken only of the secondary infection of food by pathogenic microorganisms, but as is well known the substances used for food may be primarily infected. Chief in importance in the latter category are the various entozoa and other parasites which infect animals slaughtered for food. The dangers to mankind resulting from the diseases of animals form a separate theme, which would require more time and space than this address affords for their proper consideration. I shall content myself on this occasion with only a brief reference to infections from the milk and flesh of tuberculous cattle.

It has been abundantly demonstrated by numerous experiments that the milk from tuberculous cows is capable when ingested of causing tuberculosis. How serious is this danger may be seen from the statistics of Bollinger, who found with cows affected with extensive tuberculosis the milk infections in 80 per cent. of the cases, in cows with moderate tuberculosis the milk infections in 66 per cent. of the cases, and in cows with only slight tuberculosis the milk infections in 33 per cent. of the cases. Dilution of the infected milk with other milk or with water diminished or in sufficient degree it removed the danger of infection. Bollinger estimates that at least 5 per cent. of the cows are tuberculous. From statistics furnished me by Mr. A.W. Clement, V. S., it appears that the number of tuberculous cows in Baltimore which are slaughtered is not less than 3 to 4 per cent. Among some breeds of cattle tuberculosis is known to be much more prevalent than this.

There is no evidence that the meat of tuberculous cattle contains tubercle bacilli in sufficient numbers to convey infection, unless it be very exceptionally. Nevertheless one will not willingly consume meat from an animal known to be tuberculous. This instinctive repugnance, as well as the possibility of post-mortem inspection of the meat in dressing the animal seem good grounds for discarding such meat. The question, however, as to the rejection of meat of tuberculous animals has important economic bearings and has not been entirely settled. As to the rejection of the milk from such animals, however, there can be no difference of

opinion, although this is a point not easily controlled.

The practical measures to adopt in order to avoid infection from the food are for the most part sufficiently obvious. Still it is not to be expected that every possibility of infection from this source will be avoided. It is difficult to discuss the matters considered in this address without seeming to pose as an alarmist. But it is the superficial and half knowledge of these subjects which is most likely to exaggerate the dangers. While one will not under ordinary circumstances refrain from eating raw fruit or food which has not been thoroughly sterilized, or from using unboiled or natural waters in the fear that he may swallow typhoid or cholera bacteria, still in a locality infected with cholera or typhoid fever he will, if wise, not allow himself the same freedom in these respects. Cow's milk, unless its source can be carefully controlled, should, when used as a habitual article of diet, as with infants, be boiled, or the mixed milk of a number of cows should be selected, but this latter precaution offers less protection than the former.

In most places in this country we are sadly lacking in good sanitary inspection of the food, especially of the animal food, offered for sale. One cannot visit the slaughter-house in Berlin or Munich, and doubtless similar ones are to be found elsewhere, and watch the intelligent and skilled inspection of slaughtered animals without being impressed with our deficiency in this respect. In large cities an essential condition for the efficient sanitary inspection of animal food is that there should be only a few places, and preferably only one place, where animals are permitted to be slaughtered. Skilled veterinarians should be selected for much of the work of inspection.

It may reasonably be asked that the National Government, which has already spent so much money for the study and extermination of such diseases as pleuro-pneumonia, of cattle, and hog cholera, which are not known to endanger the life of human beings, should turn its energies also to means for eradicating tuberculosis from cattle, which is a scourge not only to the economic interests of farmers and dairymen, but also to the health of human beings.

Without any pretension to having done more in this address than to sketch here and there a few principles derived from bacteriological researches concerning only some of the most widely distributed external sources of infection, I trust that enough has been said to show the folly of any exclusive dogma as to modes of infection. The ways of infection, even in one and the same disease, are manifold and various, and can never be resolved into exclusive hypotheses, such as the drinking-water hypothesis, the ground hypothesis, etc.

It follows, therefore, that it is not by sanitary improvements in one direction only that we can control the spread of preventable epidemic diseases. In one situation the improvements in the supply of drinking water check the prevalence of typhoid fever, in another place similar measures show no such influence; or again, in one city the introduction of a good system of sewerage diminishes epidemic diseases, and in another no similar result follows. We should, therefore, aim to secure so far as possible good sanitary arrangements in all directions and in all respects.

It has also been rendered evident in what has been said that infectious agents differ markedly from each other in their behavior, so that while public sanitation aims at those measures which are found to be most widely beneficial, it should not forget that each infectious disease is as much a separate problem in its prophylaxis as in its symptomatology, etiology and treatment. It will not aim to combat cholera with the means found best adapted to scarlet fever, but it will adopt preventive measures as directly to the specific end in view as possible.

In presenting to you the results of researches chiefly bacteriological concerning the scientific basis of preventive medicine, I hope to escape the accusation of onesidedness and narrowness by the statement that I do not for a moment intend to imply that the bacteriological method is our only source of accurate knowledge on the subjects which have been considered. My aim is accomplished if I have succeeded in making clear that this method has established facts which aid in a clearer conception of the causes of some important infectious diseases, in a better understanding of the sources and danger of infection, and in a more efficient selection and application of sanitary measures.

If this science of only a few years' growth has furnished already acquisitions to knowledge so important, so far reaching, may we not look forward with assurance to the solution of many dark problems in the domain of infectious diseases, problems the solution of which may yield to preventive medicine a future of usefulness and success which we cannot now foresee.

DR. PHILIP F. BRAKELY, who for forty years was the Secretary of the Medical Society of Warren County, N. J., died in Belvidere, at the age of 75, on July 3. He was a representative man in northern New Jersey, just as Dr. Wm. Elmer, who died six days before him, was an able standard bearer in the southern section of the State. Dr. Brakely was early identified with the American Medical Association, and a permanent member of the State Society. His death has been ascribed to the infirmities of advancing age, culminating in cardiac syncope.

## ADDRESS ON THE PROGRESS OF MEDICAL SCIENCE DURING THE PAST HALF CENTURY.

BY SIR JAMES GRANT, M.D., K.C.M.G.,  
PHYSICIAN TO THE GOVERNOR-GENERAL OF CANADA.

*Delivered at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June 27, 1889.*

Sir James Grant, M.D., of Ottawa, Canada, upon being called upon, rose and spoke as follows: I beg to return to you my sincere thanks for the invitation extended by a committee of this Association to be present at this meeting of the medical profession of the United States, and it is an additional source of gratification that I am asked to a seat on this platform. I am reminded of the fact that when the Marquis of Lorne was governor of Canada, the Royal Society was invited to lunch at the government house. When the health of the president of the United States was proposed, a sentiment which we Canadians fully appreciate, and which we are delighted to honor next to that of our glorious Queen Victoria, Mark Twain was asked to respond. He thanked his excellency for the compliment and was proud to be the recipient of the distinction, but regretted that being unprepared he was unable to respond. I feel very much in the same position on being called upon to speak to this large body before me. For fully twenty-five years I have been in the habit of attending the meetings of your Association at various points, and it is to me a source of pride and gratitude to be able to note the progress of that profession to which I have the honor to belong. This is an exceedingly important epoch in the history of our profession. You have just celebrated your one hundredth anniversary, which marks the progress of this great country. In entering the hall to-day, the observation dropped from a bystander that the insane doctors were meeting here. It struck me as somewhat peculiar, inasmuch as I was not aware of the fact that this meeting could appropriate that idea. It was soon cleared up as I learned that that branch of the profession met here. Let me, for a short time, draw your attention to the remarkable advance in the several departments of the profession, which has been made within the past century.

It was in 1835 that Gardner Hill, of the Lincoln Lunatic Asylum, announced the treatment of insanity by non-restraint. Prior to that time the poor lunatic was subject to be confined in the corner of a cell with chains round his neck, his arms manacled, and pendulous clubs attached to his feet in order to prevent locomotion. His food was served to him as it would be to an ordinary quadruped, and in fact the whole treatment of the insane in those days was most irrational in its character. Much credit is due to Pinel in Paris, Tuke of York, and Charlesworth in the city of

Lincoln asylum, in which the grand final experimenting of entire freedom of the insane was carried out.

We find here that in the great institutions of this country for the treatment of the insane every indication of progressive development as to the principles of treatment in cases of mental aberration have been carried into operation most successfully. You have undoubtedly great workers in the subject of psychological investigations. When in Edinburgh some years ago, Dr. Tuke, the author of that admirable work on "Insanity," remarked to me that by far the best journal on psychological medicine was that published by the late Dr. Jewell, of Chicago. The investigations of the late Dr. Gray, of Utica, are well known, doubtless, to every member of the Association. The subject of cerebral pathology attracted his closest attention, and his demonstrations by the large microscopic sections of the brain, which he was enabled to make, did much to convey an accurate idea of cerebral structure under very diverse circumstances. Strange to say that some of the most violent forms of insanity ever under the microscope have not been traced to anything like change of structure. Such, also, was the impression conveyed to me by Tuke, of Edinburgh. These, of course, may be looked upon as irregular cases, as usually insanity rarely takes place without some definable reason in the great nervous center. Under these circumstances is not the trite and laconic observation of *Punch* brought home to us with more than ordinary force: "What is matter, never mind, and what is mind, that's the matter." Pursuing this subject still further the investigations of our physiologists within the past quarter of a century have certainly accomplished much as regards our knowledge of the nervous system. Disturbed cerebral centers, frequently telegraph their abnormal condition to the peripheral surface, producing an abnormal condition of facial expression. By a process of careful analytical induction such men as Ferrier, of London, Hamilton and Seguin, of New York, and Hammond, of Washington, have been enabled to take stock of the changes and define the region of the disturbed centers. This embraces the great recent advances in the subject of cerebral localization, and is the very cue to the advances in cranial surgery undertaken by such men as Horsley, of London, McKeon, of Glasgow, and Seguin and Warren, of New York.

In looking around me on this platform, I am extremely grateful to find present one of the ex-presidents of this Association, Dr. Bowditch, of Boston, whose name is so closely associated in the subject of pleuritic effusion, and who worked so vigorously to convey his accurate impressions as regards the treatment of this important thoracic disease. Not alone have his observations

been confined to the chest, but in the domain of preventive medicine he has also been one of the pioneers. It has been well said that "an ounce of prevention is better than a pound of cure," and notwithstanding the fact that the members of the medical profession in the advocacy of sanitary science, are curtailing very effectively the means of their ordinary livelihood, and still their philanthropic efforts are never stayed where they can be of advantage to the public at large. The great public institutions of this country give evidence of the principles of sanitary science. The jails are made comfortable even for the most detected criminal. The hospitals give evidences of thorough ventilation and ample supply of light and all the modern improvements for sewage and water supply, very important factors in the treatment of the sick. The articles of diet are being carefully investigated. Milk is now known to be a prolific source both of scarlet fever and diphtheria, and in early life being a common source of diet, how necessary are the investigations of the sanitarian. Less than half a century ago, Farr, of London, gave a great impulse to the progress of sanitary science by the introduction of tabulated statistics as to the life and death rate. In the various medical institutions in this country, as well as in Canada, the subject of sanitary science is receiving the most careful consideration, and very justly so, inasmuch as it pertains most closely to the welfare of society at large. Let me draw your attention for a few moments to a great gymnasium of the human system, of which we have evidence in the surgery of the abdominal cavity. This country has reason to feel proud of what has been accomplished in this department. The name of Ephraim McDowell, of Kentucky, with you, as with ourselves, is a household word. He possessed the skill, the forethought, and the knowledge which enabled him to undertake the first ovariectomy. Following rapidly in his path came Dunlop, of Ohio, and Kimball, of Lowell, Mass., the latter of whom maintains the vigor of youth, although considerably over his seventieth year. These men constitute an intellectual tripod, if I may so term it, in the domain of abdominal surgery. Before me I see a gentleman whose name I cannot refrain from giving expression to, Dr. Senn, of Chicago, who has accomplished so much with reference to the lesions of the intestinal canal. His name will undoubtedly become a household word amongst the members of our profession. While advertizing thus personally to what your men have achieved, I feel confident you will join with me in recognizing the admirable achievements in the same line of thought brought about by such men as Sir Spencer Wells, Drs. Thornton, Bantock, Lawson Tait, and Keith, of Edinburgh. Almost every organ in this cavity has been operated on successfully, and the achievements mark beyond a doubt

the progress of surgery during the latter half of this century. There is another department concerning which I desire to allude briefly, namely, that of therapeutics. We have with us to-day Shoemaker, of Philadelphia, and Prof. Stuart, of McGill University in Montreal, both of whom are actively engaged in therapeutic inquiry. Medicines are now no longer, we hope, administered empirically; the why and wherefore are being inquired into most carefully. How the remedial agents act directly or indirectly on the blood and tissues is the subject of much physiological research. Here comes in a question of the slowing of the heart's action by digitalis and the reduction febrile states of the system by antipyretics. Much credit is due to the pharmaceutical associations of this country for the elegance of the preparations placed before the profession, so much so that the old British pharmacopœia must undergo considerable modification. There is also a marked advance in dietetics embracing peptonoids and very digestive materials introduced to tone and assist digestive function. Cod liver oil and its emulsion also occupy an important place as therapeutic adjuncts. And in addition the triturations so recently introduced are doubtless valuable as means of medicinal administration.

On my way from Boston, yesterday, I was gratified to read the instructive address of the Hon. Chauncy Depew to the legal profession, in which he referred to the representation of this country. Of the thirty-two presidents, eighteen were members of the legal profession, and during the past one hundred years, in eighty-two of that period the presidential chair has been occupied by legal lights of this country. The bearing of this subject is extremely important, inasmuch as the medical profession is concerned. In the Commons of Canada there are at least fifteen or twenty medical men, and in the Senate also quite a number of members of the medical profession. In the local provincial parliaments our profession is ably represented. Thus we have been enabled to guide and direct public opinion towards the important question of medical education. I listened with pleasure to the report of your committee on this subject, recommending the introduction of a higher standard in this country, both as to preliminary education and subsequent academic study. Having been upwards of twenty-two years consecutively in the Medical Council of Ontario, I have had opportunities of observing the importance of this question. The local Parliament of Ontario passed a bill for the formation of a Council, giving it the power to appoint examiners in medicine, irrespective of the teaching bodies, and thus guard the portals of entrance into the medical profession. Prior to this time the entrance of homœopaths and eclectics into the profession was very considerable, but now that matters have been placed on a uniform basis of

examination, except in special subjects such as homœopathy and eclectic materia medica, we find that this elevated standard has improved very materially the entire status of our profession; in fact, to-day there are very few graduating homœopaths or eclectics compared to the regular profession, greatly brought about by the introduction of the elevated standard of medical education.

In the great medical centres of this country we cannot fail to miss many of the old landmarks, men like Dunglison, Gross and Pancoast, of Philadelphia; Parker, Buck, Marion Sims, Flint, Hamilton and Van Buren, of New York; White, of Buffalo; Brainard and Jewell, of Chicago. These men gave a force, a character and an impulse to the profession recognized throughout the civilized world. Younger men are following rapidly into the path of distinction, and have achieved more than an ordinary celebrity, such as Thomas and Emmett, of New York; Storer, of Boston; and Goodell, of Philadelphia; particularly in the diseases of women. I am pleased to observe here so many younger members of the profession. To attend these meetings is a duty they owe not only to themselves but to the communities in which they are laboring. Here we receive, as it were, a bird's eye view of the progress of our profession in every department, and the very intellectual friction produces a tonic influence which sends every member of this Association home with renewed vigor in that profession we delight to honor. A young Western physician, recently visiting Paris, remarked to his professor if he knew so and so in the medical profession; the reply was that he did not. "What has he written?" was the question asked. The young physician answered, "He has not written anything so far as I know, but he has a very large practice." To the younger members of the medical profession I would say, in order to achieve a lasting reputation, record your facts, note carefully bedside observations and do not be in a hurry in drawing sudden conclusions. Thus you will be enabled to contribute your mite to the journalism of this country, and support a most commendable department of literature which guards over the best interests of our profession.

To the profession in Canada permit me to say that I consider ourselves one people. Placed as we are on either side of an imaginary Chinese wall we speak the same language, we enjoy the same literature, we take our inspirations from the same fountains of science in all that pertains to the best interests of our profession, and I will say, in as far as the unity of that profession is concerned, that the beautiful sentiment expressed by Her Majesty the Queen on the completion of the Atlantic cable applies equally well to our profession: "What God hath joined together let no man put asunder." In conclusion let me again return you my warmest thanks for the kind reception I have received and the delight I have experienced

in the presence of your great historian, Baucroft, and many other old friends I see around me still in the vigor of life. Let us then work on to do honor to our profession, to alleviate the sufferings of humanity, and in that profession to perform the important responsibilities assigned to our respective charges. And I feel I cannot do better than express the lines so beautifully written by your gifted poet who now slumbers amidst the illustrious dead of this great Republic:

"Let us then be up and doing,  
With a heart for any fate;  
Still achieving, still pursuing,  
Learn to labor and to wait."

The distinguished speaker was frequently interrupted by loud applause.

## ORIGINAL ARTICLES.

### CHRONIC INVERSION OF THE UTERUS. REDUCTION BY A NEW METHOD.

*Read in the Section of Obstetrics and Gynecology, at the Fortieth Annual Meeting of the American Medical Association,  
June 25, 1889.*

BY HENRY O. MARCY, M.D.,  
OF BOSTON.

It is my purpose in this paper to consider only chronic cases of inversion of the uterus, as they are usually presented to the attention of the gynecologist. Cases of partial inversion occurring at labor are believed to be far more common than the teachings of the text-books would lead us to accept. More than once it has occurred under my own observation, and in a recent discussion upon the subject by the members of the Boston Gynecological Society, a considerable number of cases were reported.

It was undoubtedly more frequent during the earlier practice of the midwives, when traction upon the umbilical cord was commonly practiced, in order to bring away the placenta. There is much disagreement of opinion as to the cause of inversion even in these cases, although it is conceded that the uterus is generally very flaccid and muscular contraction of the organ is either irregular or wanting. When the inversion is complete, under such circumstances, the hæmorrhage and shock are often so great as to endanger life.

When promptly recognized the reposition of the organ is generally not attended with serious difficulty. If the placenta has not been detached for the obvious reason of lessening hæmorrhage, it is better to replace, if possible, before separation. This, however, is exceptional, since a more or less partial separation takes place, accompanied by great hæmorrhage. If the cervix is firmly contracted reposition is no longer easy, but nothing is gained by delay and reduction must be accomplished regardless of difficulty. When reposition has taken place, the uterus must be supported

until it is firmly contracted. It has generally been considered wise to tampon the vagina and to retain the patient in the horizontal position, upon the back, for a considerable period, in order to prevent contraction of the abdominal muscles, but it is extremely probable that such precaution is unnecessary and ill-advised.

Intra-uterine growths, usually submucous myoma, very rarely produce inversion of the uterus. When it thus occurs the uterine contraction upon the growth causes a deflection of the fundus or place of attachment, which goes on slowly by traction from above downwards to bring about this result. The late Professor E. Martin, of Berlin, reported a case, in 1869, where a myoma the size of a fist was removed from the fundus of a completely inverted uterus in a multipara, aged 46, which had produced profuse hæmorrhage. Spontaneous reduction of the organ took place a few days later.

Langenbeck and McClintock each report a similar case. Dr. Emmett, in 1869, removed a myoma from the fundus with the *écraseur* and reduced the inversion by taxis. It is variously estimated that from 5 to 8 per cent. of the cases of inversion are due to this cause.

Several writers of prominence have maintained that irregular uterine action is occasionally the cause of inversion, and that it usually commences about one horn of the uterus. This was especially maintained by Kiwisch. Based upon this view, Dr. E. Noeggerath, of New York, has devised his method of reduction, which consists in compressing the uterine body opposite to each horn, so as to indent one of these and thus offer to the cervical canal a wedge which passes up and is followed rapidly by the other and the whole body of the uterus. Dr. Thomas endorses this method as of great value, and states that he has twice reduced an inverted uterus successfully in this way. Dr. Thomas reports a case operated upon by Dr. Budd, of New York, for the removal of a supposed fibrous polyp, the size of a hen's egg, attached to the uterine cavity near the entrance of the right Fallopian tube. Careful examination, however, showed that it consisted of one horn of the uterus, with a part of the corresponding Fallopian tube and round ligament, thus demonstrating the case to have been one of partial inversion. Reports of cases of inversion of the uterus, associated with a variety of growths, usually ascribed as cause, are to be found scattered through the literature of medicine. Pathological preparations showing this interesting condition are also preserved in a considerable number of collections.

Improbable as it may seem, it still must be accepted as demonstrated that cases of so-called spontaneous inversion have occurred. Several such cases are recorded by Dr. Thomas and others. These, however, as well as cases of spontaneous reduction, must be considered as accidental curi-

osities. It is very probable that the more careful study of cases of this character would make clear a series of causes altogether overlooked. In the Second Volume of the "American System of Gynecology," recently published, is found an excellent article upon chronic inversion of the uterus, by our distinguished countryman, Dr. S. C. Busey, of Washington. He concludes that about 87.5 per centum of all the cases belong to the puerperal variety. "Of 224 cases collected by Crampton, 196 are noted as having occurred simultaneously with the termination of labor. Of the remaining 25 cases, in 12 the accident occurred during the first hour after labor; in 7 during the first day; in 2 during the first week; in 2 during the first month; in 1 during the fifth month; and in 1 during the thirteenth month. The direct causal relation of parturition and the puerperal period to the displacement is thus very clearly demonstrated."

Inversion of the uterus is fortunately a very rare accident. "Madden estimates it to occur only once in 190,000 labors. Reeve at one in 140,000 cases, Aveling at one in 100,000. In the Vienna Lying-in Hospital, from 1845 to 1882, in a total of 280,000 labors, but one case occurred."

Crosse's<sup>1</sup> monograph upon inversion of the uterus is still to be considered as one of the most valuable contributions upon the subject. He collected the history of about 400 cases. He states that about one-third of all the cases, under whatever circumstances, or in whatever degree they occur, prove fatal either very soon or within one month. He analyzed 109 fatal cases. Seventy-two proved fatal within a few hours, most of them within half an hour; 8 cases proved fatal in from one to seven days; and 6 in from one to four weeks. If the patient survive a month the case is chronic and the immediate danger is small. But the danger recommences at eight or nine months, when the menstrual function is resumed. Many of these will die within two years. Cases as usually presented to the gynecologist, by a careful examination, should be easily diagnosed. Yet in the earlier history of uterine surgery the organ was occasionally removed, under the belief that the operator was dealing with a uterine polyp.

The treatment of chronic inversion of the uterus furnishes a chapter of exceptional interest to the surgeon. Until within the present generation the reposition of the organ was supposed scarcely possible, and if life was seriously threatened amputation was advised. It was not until about 1858 that the attention of the profession was seriously called to the systematic attempt at reduction of the uterus in chronic inversion. The few cases that had been successfully treated prior to this date had been reduced by manipulative dexterity and regarded as accidental rather than systematic.

<sup>1</sup> An essay upon "Invertio Uteri," by John Green Crosse, London, 1845.

In 1858 the late Professor James P. White, of Buffalo, published his method of reduction by continued elastic pressure. His first case occurred in 1856. His second in 1858. Dr. Tyler Smith, of London, published his method also in 1858, which is a combination of elastic pressure and taxis. Dr. White's procedures are so well known that detailed description is unnecessary. A soft-rubber, cup-shaped end of the instrument receives the fundus. A wire spring capable of sustaining ten pounds pressure is adjusted to the other end, and so arranged that it may be brought to bear against the breast of the operator. Bimanual manipulation is an important part of Dr. White's method. One hand grasps firmly the uterus thus supported, while the counter pressure is maintained upon the cervix through the abdominal wall by the other. In Dr. White's first case the inversion was of eight days' standing; in his second, of nearly six months' duration. In this last the organ was reduced after about one hour's continuous effort. In Dr. White's article upon "Chronic Inversion of the Uterus," published in the "Transactions of the International Medical Congress," Philadelphia, 1876, he concludes, based upon the experience of ten cases, "the result has been, in all the cases encountered, restoration by manipulation on the first trial, and, as is believed, without serious injury to the tissues, thus confirming the conviction that all cases are curable, irrespective of their duration."

Dr. Clifton E. Wing, of Boston, reported a case, in 1879, where he reduced an inverted uterus of about three months' duration by continuous elastic pressure. Elastic tubing was attached to the distal end or stem of a cup-shaped instrument adjusted to the fundus. These ends were drawn tight and attached in front and behind to a waist belt. The amount and direction of the force was found to be easily within control. "The evening of the second day there was evidently some gain. The evening of the third day the patient felt a little restless. . . . She slept well under a dose of morphine, but was waked in the middle of the night by feeling something 'jump inside.' On examination in the morning I found the uterus replaced and the end of the instrument extending up into its cavity." Rapid convalescence followed.

Aveling has modified the methods of Drs. White, Tyler Smith, and Wing, by giving the stem supporting the cup a sigmoid curve, so as to carry the direction of the pressure in the line of the upper axis of the pelvis. A belt is applied around the waist and fastened to braces over the shoulders. By this method elastic tension is secured. The patient must be confined to the bed, morphia given to control pain, and the bladder evacuated by the catheter. In eleven successful cases Aveling reports the average time for reduction at about forty hours, the longest being fifty-four and a half hours, the shortest nine hours.

Dr. Robert Barnes, of London, in his work upon "Diseases of Women," figures an instrument which he calls his elastic pessary. This he described and first published in the *Obstetrical Journal*, in 1873. He states "that he attempted to reinvert the uterus in 1868, by continuous elastic pressure, maintained for five days, but was unsuccessful."

The elastic pressure applied by the late Dr. Tyler Smith consisted of an air pessary, retained in the vagina by a T bandage. Barnes, Wing, and Aveling, only modified the method of Dr. White by making the pressure in a graduated elastic force minimized in amount, but which was necessarily in the same ratio greatly extended in time. No new principle was involved and the modifications of application, may, at the best, be considered of doubtful value. Manual manipulative measures, modified but systematized taxis, have also their modern exponents.

Dr. Emmett's method consists of "encircling with the fingers and thumb that portion of the body close to the seat of the inversion, which is firmly grasped, pushed upward, and the fingers then immediately separated to their utmost, at the same time the other hand is employed over the abdomen, in the attempt to roll out the parts forming the ring, by sliding the abdominal parietes over the edge." Thus the effort is systematically made to return first the tissues last displaced, rather than to bring to bear the force upon the fundus proper. This is, physiologically, eminently correct and scientific.

Courty<sup>2</sup> carried the index and middle fingers of the left hand up the rectum and with them fixed the cervix, and then continued the taxis, as advised by Emmett.

Tate<sup>3</sup> carried this method further, by the introduction of one forefinger into the bladder, the better to hold the cervix for the purpose of counter pressure. The uterus held in fixation from above downwards by fingers in the rectum and bladder, the pressure is applied by the thumbs upon the fundus.

Surgical intervention has not been wanting as an aid for the reposition of the inversion of the uterus. Such measures would naturally be applied to the constriction at the neck, the seeming objective factor to be overcome.

Dr. Barnes<sup>4</sup> writes, "For twenty years I have taught in my lectures that the unyielding cervix may be divided by incisions carried into its substance from above downwards at different points of its circumference. Pressure then applied will cause it to yield more easily. Huguier, Professor Simpson, and Dr. Marion Sims have suggested this plan." It was, however, not until 1868 that Dr. Barnes had the opportunity to carry his teach-

<sup>2</sup> *Maladies de l'utérus*. 1866.

<sup>3</sup> *Cincinnati Lancet and Observer*, March, 1878.

<sup>4</sup> *Op. cit.*, page 635.

ings into effect. After continuing elastic pressure by the method of Tyler and Smith for five days without success, Dr. Barnes secured the fundus by a noose of tape and drew the organ as far externally as seemed safe, and then incised the neck one-third of an inch deep, laterally and posteriorly. The cervix yielded and the restoration was complete, although lacerations extended quite a little from the incisions. A good recovery followed. Dr. Barnes recommended only lateral incisions of moderate depth, as an aid to sustained elastic pressure. He has since used this method with equal success. Dr. Thomas, of New York, attempted it, but the bleeding proved so very serious, from the division of the circular artery, that life was endangered. Hæmorrhage was controlled with much difficulty. About one week later he reduced the inversion by a method which he had had under consideration for a considerable period by opening the thin abdominal wall over the cervix and dilating it by a glove-stretcher instrument. This, however, was accomplished with much difficulty, owing to the elastic contraction of the cervix. It has been resorted to several times by Dr. Thomas and others, and is commended by this author as affording another means of dealing with this most distressing accident, which may be accepted in preference to amputation. In case of failure amputation may at once be advantageously performed.

The early statistics of amputation give as a result a mortality rate of 25 to 30 per cent. Although the operation for amputation is doubtless ever to be regarded as a major one, involving serious risks to life, there can be no doubt that the death-rate as shown by collated statistics is very much greater than would occur under modern surgical procedure. The comparative absence of danger now attending aseptic laparotomy would cause the profession to look upon Dr. Thomas' operation far more favorably than when first published, seeming, as it then did, a bold, ingenious, but dangerous innovation. It is, however, to be considered if access to the uterus from above gives, after all, the advantages which *a priori* had been expected. The elastic contraction of the cervical fibres is overcome only with the greatest difficulty. In illustration of this I quote from a paper by Dr. Paul F. Mundé, entitled "Laparotomy for Reduction of an Inverted Uterus," read before the Obstetrical Society of New York last October, and published in the *American Journal of Obstetrics* for December, 1888.

"Rapidly making a 2-inch incision through the abdominal wall, I pushed the uterus from the vagina upwards, so as to almost bring the ring into the wound, and, first with my fingers, then with a Palmer's steel dilator tried to stretch it apart. Failing in this, I sent for a glove stretcher, which was disinfected and inserted through the cervical ring to the very bottom of the inverted

uterus and separated to the utmost. The ring was thus completely dilated and I expected immediate reduction, but as the glove stretchers were slowly withdrawn to allow the *pari passu* reposition, from the vagina, at the instant the stretcher slipped out of the ring, the latter closed like a vise; and although the attempt was repeated again and again, no rapidity or concurrence of action in pressing the fundus upward, succeeded in anticipating the contraction of the ring. It seemed almost incredible that it should have been impossible to so dilate and keep open the ring, when it was not only easily accessible, but even visible at the abdominal incision, so as to enable me to slip the fundus back through it. But such was nevertheless the case, and my spectators will, I think, give me credit for having tried faithfully to save this woman's uterus. As a last resort I followed a suggestion of Dr. Lillienthal, my house-surgeon, who assisted me, and passed a Peaslee's needle from the vagina through the firmest portion of the fundus uteri and out of the ring and the abdominal wound, attached a long loop of the thickest silk to it, drew the loop out of the vagina and tied a piece of large, double-rubber drainage-tube to it, as a fulcrum upon which to exert traction. I chose a flexible tube in preference to a flat button of horn or metal, which were at hand, because I feared the latter might prove an obstacle at the contracted ring. Then dilating the ring with the glove stretcher, I tried to draw the fundus up through it by making steady traction on the loop of silk. But the pulpy uterine tissue gave away and the drainage-tube suddenly appeared in the abdominal wound." Dr. Mundé recognizing that no further effort for saving the uterus was justifiable drew the organ as far as possible from the vagina and ligated high up with an elastic cord. From the abdominal cavity he removed the ovaries and tubes and closed the wound. On the thirteenth day the elastic ligature was found loose in the vagina, and after this the patient made an uninterrupted recovery.

Were it possible to find easy and safe access to the cervical canal through an opening in the abdominal wall, Dr. Mundé's case emphasizes the difficulties of overcoming the elastic contraction of the cervical fibres experienced by Dr. Thomas in his first case, and which has been met also by other operators. Again, we have to consider the importance of the danger, and which, so far as I know, has not been referred to by any operator, of pressure upon the inverted Fallopian tubes, carried as they are of necessity quite within the inverted uterus. The method of Dr. Lillienthal is certainly ingenious, is philosophic, and was deserving of a better result. There can be little doubt that the tissues of the fundus were materially impaired in their integrity by the previous prolonged manipulative procedures.

In 1877 I devised a method for the reduction of

the inverted uterus by elastic pressure, the same force to be applied simultaneously upon both the fundus and cervix. This was to be effected by first tying into the cervical tissue four metallic rings. A strip of pure rubber about  $1\frac{1}{4}$  inches in width and 18 inches long was slit at either end and nearly to the middle. The ends were to be threaded through the rings and continuous traction applied. I was met with the objection that the theory was perfect, but that the rings could not be made to hold in the tissue. In order to demonstrate the fact, as well as to serve another purpose, which seemed to me might possess material advantage, I applied rings as above suggested to a cervix uteri which I desired to dilate and thus carried by elastic force a conical plug into the cervical canal. When the sutures were deeply applied the cervical tissue was found to bear any reasonable amount of tension protracted through several hours. After a long series of experimentation for the purpose of dilation of the cervix these comparatively crude and clumsy efforts led up to the construction of the repositor, which in its present form seems to answer every requirement. After waiting twelve years the following case gave the opportunity of testing its value.

Mrs. B., æt. 33. Healthy girl. Menstruated at 14. Married at 30. Well and regular in menses until marriage, three years since. Eighteen months ago aborted at the third month. June 19, 1888, was delivered at term with instruments, under ether, by Dr. James McDonald, of Boston, after twenty-four hours of severe labor. Made an imperfect recovery, flowing more or less constantly until operation for the reduction of the inverted uterus, September 8th. Was in bed three weeks and had been confined to room since birth of child. Condition first determined by Dr. McDonald in August. He feels quite sure the inversion did not take place at time of labor. I first saw Mrs. B. the day of the operation. Patient markedly anæmic. Dr. M., assisted by Dr. Lynch, had made a prolonged attempt, under ether, that morning at reduction by taxis, without avail. Endometrium everywhere a bleeding surface. The cervix constricted to render the organ distinctly polypoid in shape. Could feel the edge of the cervical ring. I introduced, with a large, full-curved Hagerdon needle, long ligatures of No. 8 braided silk deeply through the cervical tissues on each of the four sides, equidistant, and brought them into fixation with the repositor. A steady, uniform pressure was kept, at about 8 pounds by the scale. After ten minutes the cervix had yielded perceptibly and in fifteen the organ was half inverted, the cup being covered by the retracted cervix. The operation was completely finished and instrument removed in twenty-six minutes from commencement of pressure. No shock followed and recovery was rapid. After five weeks the patient flowed to soil two or three napkins.

The fourth regular menses occurred Dec. 20th. Dec. 28th visited office; not seen before since operation. Was in perfect health. Uterus not tender, not enlarged, movable and normal to feel. The pressure is applied by means of a spring concealed in the handle. The scale is graduated up to 15 pounds in order to determine the amount of force used.

In reviewing the various methods devised for the reduction of the inverted uterus it will be observed that the place of counter pressure is of necessity found in the vaginal attachment of the organ. In order to bring the force to bear upon the cervix the method of bimanual manipulation, as devised by White, Sims, and others, was appreciated as of great importance. First, by the hand extended over the abdomen, then by two fingers introduced into the rectum, this being further supplemented by the finger introduced into the bladder.

In the method for the application of continued elastic force, first advocated by Drs. Tyler Smith and Barnes, and perfected by Dr. Aveling, the fixation of the cervix is necessarily abandoned and the counter pressure is brought to bear directly upon the vagina and surrounding organs. The force thus applied, at the best, acts only indirectly on the cervical ring, which is the chief criticism of the method. Theoretically a force should be applied to draw down upon and invert the constricted cervical fibres at the same time that pressure is made upon the organ from below upwards. This should be elastic and continuous, but not too great. This force Dr. Emmett wisely recognized in its application by his method of taxis. As illustrated in the case of Dr. Mundé, the dilatation of the cervix, at the most, is only one factor of the problem. Let that force be converted into one acting at the same time from below upwards upon the fundus and the elastic constriction becomes transformed into a power to serve for the reduction of the organ. When applied in this manner the cervical fibres, little by little as they dilate, receive within their grasp and retain the returning portion of the organ. My method is simple and effective. The criticism of a number of the profession is, "I wonder that it has not been thought of before." I exhibited my repositor to Dr. Priestly, of London, when my guest in Boston, a little before the discussion of Dr. Mundé's paper, and he was kind enough to speak favorably of my method at the discussion above referred to. At the same meeting Dr. B. McE. Emmett exhibited an instrument which he had recently devised. It consists of a ring on three stems which is to encircle the cervix. The reinversion is to be accomplished by passing stitches through the border of the cervix and making traction outward over the rings, at the same time pressure is made from below upwards. Dr. Emmett recognizes, as I claim, that counter

pressure to be of value must act upon the cervix itself.

By whatsoever manner applied, it is certainly rational to expect that the reduction of the inverted uterus would be best accomplished by forces acting at the same time in opposite directions. As another means of securing this, Dr. John Byrne, of Brooklyn, has invented a repositor which consists of a cup for the reception of the uterus, at the bottom of which is placed a movable disc attached to a stem which can be projected upwards by means of a screw. In conjunction with it he uses a bell-shaped instrument placed over the abdomen, in order to fix the cervix, through the center of which a plug is projected by a screw attachment, for the purpose of dilating the cervix. In one or two instances this instrument has been used with a satisfactory result. Even so ingenious an instrument, although believed by Skeene to be the best devised is radically faulty. The abdominal wall and bladder, possibly other organs, must be involved between the opposing forces, and fixation of the cervix can never be absolute while there is no means of determining the amount of force applied. If, however, a uniform elastic pressure can be brought to bear at the same time, in the opposite direction, upon both fundus and cervix, it is a manifest gain. If this power is so applied that it is at once, one and the same force, it is possessed of still greater advantage. To place it entirely within the control of the operator without possibility of affecting any other organ, and reducing the power to one of actual observation, as given in pounds, is a still further manifest advantage. All these are rendered as constant and well-known factors in the application of the repositor which I offer the profession for trial and, if found worthy, adoption.

## MEDICAL PROGRESS.

### CONCERNING GLYCOGEN IN THE MUSCLES.—

E. KÜLZ found that the quantity of glycogen contained in the muscles of the frog is increased under the influence of daily subcutaneous injections of grape sugar, even after extirpation of the liver. It seems, therefore, that the muscles are capable of making glycogen without any assistance on the part of the liver. This conclusion has recently been attacked by Laves. He extirpates the liver of geese and chickens after giving them a meal of barley and oats; ascertaining the amount of glycogen in a fragment of the pectoral muscle immediately before the operation, he repeats the determination some hours (one to thirteen hours) after the extirpation of the liver, and continually finds less glycogen at the second test. He concludes therefrom that the pectoral muscle

is incapable of producing glycogen, in the absence of the liver, at the expense of the feculents in the nourishment.

Schmelz (*Zeitschrift für Biologie*, xxv, p. 180, 1888) repeated Laves' experiments on chickens whose livers had not been extirpated, in this way that he ascertained the amount of glycogen in the muscles before and after a meal rich in hydrocarbonates (barley cane sugar), and he discovered that even twenty-four to thirty-six hours after the meal the muscles did not show yet an increase in glycogen, although the liver was intact. It is, therefore, hardly surprising that Laves discovered no increase of glycogen after the liver had been extirpated, and the experiments of Laves can only serve to settle the question raised by E. Külz. Schmelz completes his work by drawing a parallel between the results of determinations of glycogen by weight and by circumpolarization. He recommends the determination by polarimeter (originated by E. Külz), as expeditious and sufficiently exact.

Luchsinger stated that glycogen disappeared much more rapidly from the muscles than from the livers of animals which had been given no food for a long time, and that this substance did not exist any more in the muscles after a few days' fasting. He drew the conclusion from it that glycogen should not be considered as an indispensable constituent of muscle-fibre and as the source of muscular energy.

Aldehoff (*Zeitschrift für Biologie*, xxv, p. 137, 1888) has taken up this question under the direction of R. Külz, using for the determination the method of R. Külz and A. Cramer. He finds that under the influence of fasting, in the chicken, the pigeon, the rabbit, the horse and the cat, the glycogen diminishes less rapidly in the muscles than in the liver, and that even after a protracted fast the muscles are still relatively rich in glycogen. The muscles of two horses which had received no food for nine days furnished the highest figures of glycogen (2.43, 1.34, 1.28 and 0.98 per cent.) which have ever been found in muscular tissue. The hearts of these two animals contained 0.82 and 0.58 per cent. of glycogen.

The results of determinations of glycogen made by Manché (*Zeitschrift für Biologie*, xxv, p. 163, 1888), by means of Külz' method, confirm in general the statements of Weiss and Chandon: diminution of glycogen in the muscles through tetanization of the muscles or through ligation of the nutrient arteries; increase of glycogen through cutting of the motor nerves.—*Revue des Sciences Médicales*, No. 66, 1889.

ON THE TREATMENT OF TABES BY SUSPENSION.—DUJARDIN-BEAUMETZ tried this treatment on twenty patients, with the following results: In most cases at first an improvement is noted. The patient feels stronger and finds incoördination di-

minishing; the lumbar pains are also less intense. But this improvement does not continue and ceases after two or three weeks. In some cases failure is total, and not the slightest improvement is obtained. The author is as yet unable to say why in some cases this method is effective and in others it is a failure.

So far no experimental evidence of the improvement obtained had been given; it has been furnished by us by using Marey's method. It consists in the reproduction by photography of the attitude of a patient in walking. For this a photographic apparatus is necessary, provided with an interrupter which makes it possible to take pictures in a small fraction of a second. A healthy individual is dressed in black and made to walk before a dark background, electric lamps are fastened to the head, the shoulder, the hip, the knee, and the ankle. A series of illuminated points is thus obtained which connected constitute a schema of the normal walk. The same procedure gone through with an ataxic patient furnishes the picture of the walk peculiar to individuals afflicted with tabes. The pictures taken after the suspension has been performed several times, show that the walk of the patient approaches very near to the normal. This is an absolute scientific proof of the beneficial influence of suspension. As to the mode of procedure the following should be remembered: It is important that the chin and nape of the neck are properly supported, and also that the patient is supported at the armpits. At first the patient should be left suspended for a very short time only, about fifteen to thirty seconds; gradually this is increased until we arrive at the maximum of three minutes. It has been claimed that there is no danger in prolonging considerably the time of suspension, but Dujardin-Beaumetz thinks this is wrong and might result in grave accidents.

Regarding the question, how suspension acts in an ataxic patient, and how it is that this method not only brings about a diminution of the inco-ordination, but also relieves the lightning-pains of patients with tabes, he says: "Against these lightning-pains the elongation of the nerves has been practiced, first by Langenbach, in 1879, afterwards by Debove and Gillette, in France during 1880. Elongation of nerves or nephrosteny was first used in therapeutics by Nussbaum, in 1872, later on by Billroth. In 1876 Verneuil applied it to the treatment of tetanus. According to him elongation acts like an incomplete section of the nerves. Vogt maintains that elongation produces its favorable results by acting upon the neurolema, the pulling causing a rupture of the vessels of the neurolema and the displacement of the nerve-fibrils in the same. I believe that suspension acts in the same way. It is probable that the sensitive cells of the marrow are changed in their molecular state."

However this may be, it is possible in certain cases to obtain some benefits from suspension in patients with tabes, and it would be wrong not to try this method for the cure of an affection as painful as locomotor ataxy.—*Journal de Médecine de Paris*, May 5, 1889.

ON REDUCTION OF NITRATES THROUGH CHOLERA BACTERIA.—DR. PETRI has made a series of experiments which yielded the following results:

1. Cholera bacteria reduce in their growth nitrates to nitrites.

2. The usual culture media, especially gelatine, and often also common cooking salt contain not inconsiderable traces of nitrate.

3. The red cholera reaction is accomplished through the medium of these impurities, *i. e.*, through the reduction of the nitrates.

4. An oxidation of decomposed ammonia through the vital action of the cholera bacteria is not yet proven and is improbable, in view of the fact first mentioned.—*Centralblatt für Bakteriologie und Parasitenkunde*, No. 18, 1889.

EXPERIMENTS REGARDING THE PRODUCTION OF THE VESICULAR MURMUR.—DEHIO (of Dorpat) says: Contrary to the theory according to which the vesicular murmur results solely from the propagation of the tracheo-glottic murmur to the parenchyma of the lung, the vesicular murmur can be plainly distinguished on auscultation, despite the intensity of the wheezing, in cases of stenosis of the larynx. Besides, on auscultating the lungs after Dehio had substituted a simple rubber tube for the trachea and larynx, he could distinctly hear a vesicular murmur which could only be attributed to a transmission of the concussion in the interior of the alveoli of the residual air by the column of inhaled air.—*La Semaine Médicale*, No. 17, 1889.

THERAPY OF DIPHThERIA.—DR. BURGHARDT has been making for seven years experiments in the cure of diphtheria by blowing a mixture of sulphur and quinine in equal proportions into the larynx, on the tonsils, into the nasal cavity and into the pharynx. These applications were made twice every day, and nothing must be taken for two hours afterwards; spitting must also be avoided. The powder is odorless and does not produce any disagreeable symptoms. Immediately after the application the patient is quieter, fresher, the fever ceases, the feeling of weakness leaves him. The applications are continued after all symptoms have disappeared. Burghardt has not met with a single failure. Of 33 cases, some of which were very dangerous, not one terminated fatally. Time of cure two weeks.—*Wiener Medizinische Wochenschrift*, No. 17, 1889.

SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JULY 20, 1889.

PREVENTIVE INOCULATION.

A lecture that should receive a great deal of attention from the world of medicine is the Croonian lecture on "Preventive Inoculation," recently delivered by M. ROUX, in behalf of M. Pasteur. It is almost eight years since the great scientist laid before the members of the International Medical Congress assembled in London an account of the researches, carried on in his laboratory, on preventive inoculations for chicken cholera and splenic fever. Has the work then begun fulfilled its promise? What place have the principles that it involved in the science of to-day?

In speaking of preventive inoculation we need not stop to consider the great discovery of Jenner. He showed that it is possible to protect ourselves from a dreaded disease by inoculation with a trivial one; but he gave no general method leading to the prevention of other infectious diseases. The discovery of the power of artificially attenuating—or weakening—a virus does furnish us with a veritable method of preventive inoculation; and it has, says M. Roux, given us an uninterrupted series of good results. In revealing the nature of ferments Pasteur taught us the nature of the poison of infectious diseases. We know—or think we know—that viruses are living beings, microbes, and that the development of microbes in the living body produces the phenomena of infectious disease. The processes by which we are enabled to obtain the culture of microbic ferments in a state of purity is the same

that has enabled us to obtain pure cultures of microbic virus outside of the body. The indispensable condition of success in these cultivations is absolute purity. Having obtained them in a state of purity can we not modify them by cultivation in the same way that other plants are modified? We know that many plants that are poisonous in a wild state are harmless or edible in the cultivated state. To modify the viruses by special modes of cultivation was the task to which Pasteur set himself.

Pasteur's first attenuated virus was obtained while studying chicken cholera. His experiments showed that the viruses of infectious diseases are no more the unchangeable entities they were supposed to be, but that, like all other living beings, the microbic virus is susceptible of modifications that heredity perpetuates; that above all, it is the virulent character that is modified, and that this modification can be produced artificially, and regulated according to the wishes of the experimenter. He established the attenuating influence of the air, and explained how the activity of a virus, under natural conditions as seen in an epidemic, is preserved or exhausted, and how the same infectious malady may be sometimes malignant and again light. All that was claimed by Pasteur in regard to chicken cholera was confirmed by him in his inoculations for anthrax—as is now admitted by Koch and others that contested Pasteur's claims. And taking into consideration the fact that we can increase as well as decrease the virulence of a virus, is it rash to believe that in the course of ages new forms of virulence have been evolved, and that the experiments on the variation of virulence have thrown a flood, and will throw a greater flood of light on that obscure question, the origin of new virulent diseases? We see how one and the same kind of microbe can produce diverse morbid effects; how, when it is active or virulent, it causes a general disease, rapidly ending in death, and in its passive or attenuated condition it produces only a special local lesion.

Almost all physicians are now familiar with Pasteur's investigations in regard to *rouget* or swine fever. The extraordinary fact was brought out by Pasteur and Thuillier in these inoculations that as the strength of the virus increases for the rabbit it is diminished for the pig; so much so

that, after a sufficient number of passages of the virus have been made through the rabbit, it has become vaccine for swine, and able to exempt them from the fatal forms of the malady. The question now arises, what would happen with certain human diseases if they were made to pass through a number of different kinds of animals? This process we can see to a certain extent in nature, and gives fresh support to the idea that the vaccine of small-pox is modified by its passage through the horse and cow. We are all familiar with the great controversy in regard to Pasteur's preventive inoculation for rabies—and we know the verdict of the English Commission, which should silence all objectors when taken in connection with the facts. The remarkable point in the discovery of the preventive inoculation against rabies is that the virus itself has not been discovered. As yet it is known to be a microbe by analogy only, since no one has been able to isolate it. Thus, since it cannot be cultivated in flasks and tubes, Pasteur has been obliged to cultivate it in rabbits, and he has been able to do this so easily and with such regularity that the cultivations are ready for use at a specified time. This is one of the strongest examples of the power of the experimental method as applied in medicine—the prevention of a malady the absolute virus of which is still unknown.

The greatest source of danger from microbes is in the poisonous products they form—their ptomaines, a striking example of which is seen in the case of diphtheria. The diphtheritic bacillus does not grow in the interior of tissues, but only on the surface of mucous membranes. The organism is poisoned by the ptomaines formed by the bacillus. These products are found with great difficulty in the body of an animal dead of an infectious disease, since the complex surroundings of the tissues is unsuitable for such research, and the microbes of decomposition themselves form ptomaines. But in cultivations in flasks and tubes we can find these products of the pathogenic activity of the microbes. The first experiments of this kind were made by Pasteur with the microbes of chicken cholera. The chemical products obtained by cultivation of these microbes are capable of causing the symptoms of the disease. In infectious diseases, therefore, the cause of death is poisoning, and the microbes are not only the means of spreading the disease, but also the makers of the poison.

These facts have a distinct bearing upon the question of preventive inoculation. When these chemical products of pathogenic microbes are introduced little by little into the bodies of animals, in such manner as to avoid causing speedy poisoning, but so as to accustom the animal gradually to their presence, the animal becomes refractory to toxic doses, and to the microbe itself. Thus, while formerly immunity could be secured only by the introduction of the microbe itself into the organism, it can now be secured by introducing the chemical substance into the tissues; these vaccine substances being the same that are known to be the cause of death in infectious diseases. And while we can reason only from what we know, we can say that, since these experiments on vaccination by means of soluble substances without microbes have been successful in various maladies, it is but natural to infer that their field of usefulness will be largely widened in the near future. It may be possible, indeed, as Roux points out, to protect ourselves from one malady by means of another; it is necessary only that the microbes of the two diseases should produce similar chemical substances.

What explanation can we give of the immunity conferred by preventive inoculation? At present we can best explain it by saying that when small quantities of the attenuated virus are introduced into the tissues the leucocytes—or phagocytes—accustom themselves to its presence, and when the active virus or microbes are afterwards injected the phagocytes attack and destroy them. But the phagocytes of the non-refractory animals cannot swallow and digest the active microbes, and cannot prevent their development. Immunity is the result of the habituation of the cells to the poisonous products of the microbes.

#### INTERNATIONAL COURTESIES.

The medical profession of Canada was ably represented at the annual meeting of the Association at Newport.

The eloquent address of Sir James Grant was greeted with rounds of applause, and its noble sentiments met with generous response. In this issue of *THE JOURNAL* a brief abstract of the address will be found.

Another worthy representative of the profession was Professor James Stewart, Registrar of Mc-

Gill University, one of the editors of the *Montreal Medical Journal*. The able articles which have emanated from his pen have been widely quoted. A hearty welcome was accorded to the entire delegation. It is to be hoped that at the next annual meeting, when it shall convene at Nashville, the American Medical Association will be honored with a like representation, from Canada.

#### THE RUSH MONUMENT FUND.

Had Professor William Pepper, in his eloquent address been able to speak to the entire membership of the Association, and had they listened to the stirring appeal of the Secretary, Dr. A. L. Gihon, doubtless the entire amount of money needed for the erection of the Rush Monument would have been contributed upon the spot. From the generous responses there made, it is confidently believed that a later concerted movement will accomplish this result. As a reason for their not appearing in their regular order, in the published proceedings of the Association, it should be stated that it was deemed advisable to hold the address of Dr. Pepper and the report of Dr. Gihon for use in that connection.

#### THE ENTERTAINMENTS.

The provisions made by the Committee of Arrangements, by the citizens of Newport, and by the medical profession of the State of Rhode Island, were in every respect all that could be desired, and nothing but an enthusiastic interest in the real work of the Association could have prevented its members from giving themselves over to a continued round of most attractive entertainments at the City of Newport. Let not the loyalty of the Association to its work in hand lead the good people of that city and State to infer that their generous hospitalities were not, to the fullest extent appreciated.

A day never to be forgotten was that when—after the Association-work was over—the Rhode Island Medical Society treated their guests to an old-fashioned “clam-bake” on the shores of Narraganset Bay.

#### THE JEWELL LIBRARY.

The “Jewell Library” has lately been secured as the nucleus of a great medical library for Chicago. It contains about three thousand volumes

which embrace the most valuable medical literature published up to the time of Dr. Jewell's death. The necessary subscriptions were secured from a few medical men in an incredibly short time. Thus a valuable collection of medical works has been saved from being scattered under the auctioneer's hammer and the library of one of the most devoted doctors Chicago has ever known is again made available to every reader. It is expected that the Chicago Public Library will take care of these books and the additions which will be made to bring them down to the present time, until a suitable building is provided for their reception. Such building, to render the library accessible, must be centrally located. This will add greatly to the primary outlay. It is to be hoped that some Dr. Pearson will liberally endow this library of medicine.

#### EDITORIAL NOTES.

##### HOME.

DR. JOHN S. BILLINGS, of the Surgeon-General's office, Washington, D. C., has had conferred upon him by the University of Oxford, the honorary degree of D.C.L.

DR. DANIEL H. WILLIAMS, of Chicago, has recently been appointed by the Governor, a member of the State Board of Health of Illinois.

DIPHTHERIA has been prevalent at Astoria and Stineway, both places being within the jurisdiction of Long Island City; and that city, owing to a deadlock among its officials, is in a bad sanitary condition.

NEW MEDICAL SOCIETIES IN MISSOURI.—We are pleased to learn from the *Kansas City Medical Record*, that the growth of county, district and Section Societies in Missouri is very satisfactory, new ones being reported nearly every week. This is, as it should be, and we hope we may be enabled to chronicle in the near future the same activity among the profession in other States.

THE PSYCHIC LIFE OF MICROÖRGANISMS.—*The Open Court* for July 11, publishes the reply of George John Romanes, LL.D., F.R.S., to the criticisms of M. Alfred Binet on his psychological work in its relation to microörganisms.

THE CHICAGO POLICLINIC.—The following

well-known physicians have been added to the Faculty: Dr. J. H. Etheridge as Professor of Gynecology, and Dr. F. D. Porter as Professor of Medicine.

**A NEW HOSPITAL.**—The Michigan State Legislature recently appropriated \$50,000 for the erection of a new hospital at Ann Arbor. The citizens have just supplemented that amount by voting to issue bonds for \$25,000.

**A MEDICAL EPISODE AT YALE.**—At the recent Yale Commencement two of the favored guests took snap shots at the profession of medicine. Mr. Depew manufactured the following: "I once knew a doctor who secured board with an undertaker because he thought that it would improve his business. He said he always knew when the undertaker's business was good, for then there was ice on the butter and flowers on the table."

It is interesting to note the conspicuous ability of Mr. Depew, the great after-dinner undertaker, to grapple with the financial problems involved in such *grave-undertakings*.

Mr. Clemens (Mark Twain) aimed his alleged wit "against the doctors," who, he says, have reduced their labors and increased their charges: "The doctor of to-day does not cart his medicines 'round in a wagon, but carries them in a portmanteau; he puts three drops of nothing in a glass of water and asks you to furnish the water; a month later you will find the water charged in the bill and you will have to pay for it, too."

As men are willing to pay liberally for novelties, we think Mark should pay for the water.

On the same occasion Mark Twain accused President Gilman, of Johns Hopkins University, of having neglected the rudiments of his education, especially spelling, since he did not know how "to spell 'John' correctly."

Mark is the last man that should criticise, since he has always contended that orthography was one of the "*liberal arts*."

#### FOREIGN.

**IN INDIA** the Legislative Council has drafted a bill on the leprosy question—including segregation and medical care.

**IN AUSTRALIA** the Medical Society of Victoria and the Victorian Branch of the British Medical Association recently met to discuss the Bill to amend the Medical Practitioners' Act of 1865, when it was resolved to support the Bill. The

number of insane persons in South Australia on Dec. 31, 1888, was 758—430 males and 328 females.

**IN CHILI** the Government has created a "Superior Council of Public Hygiene," consisting of seven members, whose duty it shall be to advise the Government in everything that relates to the public health throughout the Republic. The Council has a laboratory for chemical analysis under its control.

**IN RUSSIA**, at a recent meeting of the St. Petersburg Deutscher Aertzlicher Verein, Dr. Magawly cited three cases of double central amblyopia, in two men and a boy, caused by looking at an eclipse of the sun with unprotected eyes. After a prolonged stay in a dark room and subsequent wearing of dark protecting spectacles all the patients permanently recovered their sight.

**IN GREAT BRITAIN** we glean from our exchanges several items of interest. Lord Raudolph Churchill will introduce a draft Bill in the House of Commons for the amendment of the constitution of the College of Surgeons. Sir James Paget has been addressing the citizens of Oxford in support of the extension of the Eye Hospital of that city. The common iliac artery was ligatured for a large and rapidly increasing aneurism of the external iliac, by Mr. Clement Lucas, in Guy's Hospital, recently; the patient is doing well, the circulation being well maintained in the foot. The Council of the Royal College of Surgeons in Ireland has passed a resolution congratulating Sir George Porter on the honor conferred on him by the Queen, and through him to the College of Surgeons. Sir George was recently created a Baronet.

**CELLULOID MANUFACTURE DANGEROUS.**—The French Government has ordered an official investigation into the dangers to life and other interests attending the making of celluloid. During two years three accidents, in each case having occasioned serious injury and loss of life, have occurred at factories making this inflammable material. It is manifest that some form of restriction, as to locality, must be ordained for this kind of work. The process of making this substance involves the use of a considerable proportion of gun-cotton, which is too explosive and inflammable to be permitted to be used in thickly settled neighborhoods.

## SOCIETY PROCEEDINGS.

### AMERICAN MEDICAL ASSOCIATION.

#### Official Report of the Fortieth Annual Meeting.

The American Medical Association convened at Music Hall, Newport, Rhode Island, on June 25, 1889, at 11 A.M.

The Chairman of the Committee of Arrangements, DR. H. R. STORER, called the meeting to order and introduced the Rev. Thatcher Thayer, D.D., who invoked the blessing of the Almighty upon the Assembly. Dr. Storer then announced the programme of the entire session and the location of the halls for Sections.

The President, Dr. W. W. Dawson, Ohio; Vice-Presidents, Drs. W. L. Schenck, Kansas; Frank Woodbury, Penna.; Henry O. Walker, Mich.; the Permanent Secretary, Dr. William B. Atkinson, Penna.; the Assistant Secretary, Dr. V. M. Francis, Rhode Island; the Treasurer, Dr. Richard J. Dunglison, Penna., were present.

On motion, reading of the list of members registered was omitted.

Letters of regret from several members of the United States Cabinet and others were read by the Chairman of the Committee of Arrangements.

Invitations were read and accepted for the members to visit the various public buildings, Fort Adams, Fort Wolcott, the U. S. Naval Torpedo Station, the U. S. Naval Training School, the U. S. Life-Saving Station, the Historical Society's building, the Redwood Library, the Newport Hospital, etc.

His Excellency, Herbert W. Ladd, Governor of Rhode Island, welcomed the Association in a brief speech, and was followed by Dr. James H. Eldredge, an Ex-President of the State Medical Society of Rhode Island.

(See page 14.)

The deaths of Dr. F. H. Rehwinkle, Chairman of the Section of Dental and Oral Surgery, and of Dr. J. B. Hunter, of New York, were announced.

On motion, all the physicians of Newport not otherwise entitled to be present were made members by invitation.

Reference having been made to the failure to obtain reduced rates on the railroads, on motion of Dr. J. C. Culbertson, the subject was referred to a special Committee consisting of Drs. Culbertson, W. L. Schenck and J. H. Musser.

The Address of the President, Dr. W. W. Dawson (see page 1), was read by Dr. J. A. Larabee, of Ky., as Dr. Dawson was suffering from an affection of his eye.

Vice-President Dr. W. L. Schenck occupied the Chair.

On motion of Dr. W. Brodie, of Mich., a vote of thanks was tendered to the President for his very able and interesting Address, and it was referred for publication.

On motion of Dr. A. L. Gihon, U. S. Navy, the President was requested to telegraph to the venerable Dr. D. Humphreys Storer, of Boston, an Ex-President of the Association, a filial greeting and regret that he was absent from the meeting.

On motion, the Association adjourned until 10 A.M. on Wednesday.

#### SECOND DAY, JUNE 26.

The President called the meeting to order at 10 A.M.

Prayer was offered by Right Rev. Thomas M. Clark, the Episcopal Bishop of Rhode Island.

After some announcements by the Committee of Arrangements, the President announced that the Committee on Railroads would meet for a consultation and report on Thursday.

The Permanent Secretary read the names of the Nominating Committee, as follows:

Ark., P. O. Hooper; Cal., J. W. Graham; Conn., J. A. Stokes; D. C., Dewitt C. Patterson; Ga., J. B. S. Holmes; Ill., J. S. Marshall; Ind., S. J. Cook; Ia., W. F. Peck; Kan., J. E. Minney; Ky., J. M. Mathews; La., J. L. Bland; Me., F. Hitchcock; Md., John Morris; Mass., E. H. Warren; Mich., W. Brodie; Minn., John H. Murphy; Mo., Isaac N. Love; Miss., J. D. Dabney; N. J., W. Perry Watson; N. H., L. G. Hill; N. Y., E. D. Ferguson; N. C., W. J. Jones; Neb., J. O. Carter; Ohio, W. S. Christopher; Penna., W. H. Parish; R. I., J. L. Collins; S. C., S. M. Orr; Tenn., G. C. Savage; Texas, A. Van Gasken; Va., L. Robinson; Vt., H. D. Holton; W. Va., ———; Wis., W. T. Galloway; U. S. Army, G. Smart; U. S. Navy, J. L. Neilson; U. S. Marine-Hospital Service, W. H. Long; Utah, J. F. Bascom; New Mexico, W. H. Ashley.

On motion, this Committee was instructed to meet immediately.

Dr. Wm. Pepper, of Penna., then delivered the Address in Medicine, which will appear in full in THE JOURNAL.

Dr. A. L. Gihon, Chairman, read an Appeal on behalf of the Rush Monument, which will be published in the same issue with Dr. Pepper's address.

The Permanent Secretary read a reference from the Section on Gynecology, asking that the paper by Dr. Storer on "The Medals of Dr. Rush," be read before the General Session at this time. This was granted.

On motion of Dr. M. L. Herr, of Penna., it was agreed that one member of each County Medical Society in the Union be appointed to solicit funds for the monument. A recess was taken to permit the members to make their offer-

ings to the fund, which resulted in the collection of \$264.50.

The amendments to the Constitution and By-laws being in order a motion of Dr. A. Garcelon, of Maine, to postpone them until Thursday was negatived. The amendment to strike out the last clause of or paragraph of Sec. 7, relating to individually affixing names to the Constitution and Regulations of this Association was adopted after a full explanation of its purport by Dr. N. S. Davis.

Vice-President Dr. F. Woodbury in the Chair.

Dr. Culbertson moved that the whole matter of the other amendments be referred to the Board of Trustees, with the Secretary.

On motion of Dr. J. B. Murdoch, Penna., this was laid on the table.

The next amendment proposing many changes in the Sections was taken up and Dr. N. S. Davis moved to postpone all except the first paragraph. After some further discussion, on motion of Dr. Larrabee to lay this on the table and indefinitely postpone, it was carried by a large majority. A motion to reconsider this action was, on motion of Dr. Gihon, laid on the table.

The amendment providing for a General Committee, or Council, was next considered. A motion by Dr. C. R. Earley, Penna., to indefinitely postpone the entire subject was lost. After much discussion by Drs. Davis, Larrabee, Murdoch, Scott, Vaughan, Millard, Connor, Quimby, Edw. Jackson and Baldy, the amendment was rejected.

The Permanent Secretary read the following communication from the Section on State Medicine:

*Resolved*, That the American Medical Association is of opinion that it is a duty devolving on all Nations to take measures to eradicate any plague centre from their territory, that the existence of such plague centres is a menace to all other Nations, and that our State Department be requested to take measures through proper diplomatic channels for the conveyance of this opinion to the Government deemed obnoxious to the opinion as herein expressed.

On motion the action was accepted.

On motion the Association adjourned until Thursday at 10 A.M.

### THIRD DAY, JUNE 27.

The President called the Association to order at 10 A.M. Prayer was made by Rev. Jas. Coyle, of Newport.

After announcements by the Committee, Sir James Grant of Canada, and Dr. H. I. Bowditch, were invited to seats on the platform.

Dr. Grant responded to the invitation by a speech, in which he reviewed the valuable work done by the members of the profession in the United States. (See page 84.)

Dr. P. O. Hooper, of the Board of Trustees,

read their report, showing the work done in publishing THE JOURNAL, the property on hand, etc., and that THE JOURNAL was now free from debt.

### REPORT OF THE TRUSTEES FOR THE PUBLISHING OF THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, FOR THE YEAR ENDING JUNE 30, 1889.

The trustees of the American Medical Association for the publication of its Transactions in Journal form, beg leave to make their annual report.

THE JOURNAL, as is well-known to the members, is now within a few days of having completed its twelfth volume and sixth year of publication. The wisdom of the change from an annual volume containing simply its Transactions to that of a weekly issue embracing the papers read before the Association, and such other contributions of interest as its editor may select, is conspicuously apparent, and has the fullest indorsement of the Association.

It is observable that since the starting of THE JOURNAL, the attendance at the annual meetings have been better, and the dues from absent members have been more generally paid, and thereby our income increased from less than \$5,000 in 1883 to over \$15,000 in 1889. The report of the Treasurer will show in detail the financial condition of the Association which is that of THE JOURNAL. From the beginning of the enterprise it has been the desire of your Trustees, in addition to the publication of the Transactions of the Association, to produce a first-class medical journal. The plan, or means placed at the disposal of the Trustees, was at first very diminutive and tender, and had to be fostered with the greatest care and economy, that we might have a journal of any kind. The Trustees were ably assisted in this delicate and arduous duty by the zeal and ability of the editor—the father, patron and friend of this Association. He has received our thanks, and deserves your hearty commendation for the very valuable services he has given to its establishment.

From the small and uncertain resources available at the beginning, this journal has now attained a sound financial basis, and is to-day the equal, if not the best in the country, and with greater means at our disposal, and the services of a more complete corps of writers which can then be employed, we expect to place it in the very front rank of medical periodicals.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is now honored and everywhere respected, and its location coveted by various cities, publishers and commercial interests.

It has won this high position by its just and independent course, having no enemies to punish or personal interests to serve. In its course it has been, is, and will continue to be loyal to the med-

ical profession and the best interests of the American Medical Association.

From the report of the acting editor for the JOURNAL year ending March 31, 1889, the Trustees make the following extracts which concisely presents the main facts:

*Weekly and Total Circulation.*—At this date, March 31, 1889, the regular weekly circulation of THE JOURNAL is 4,633, of which 4,309 go to members and subscribers, and 324 to exchanges, foreign and domestic, and advertisers. The total number printed each week is 5,000 copies being 367 in excess of the number required for the regular mail and express lists. An average of 75 are lost by spoilage, as many more go for extra copies to contributors, leaving on file about 200 copies out of which to supply samples, and single copies to complete files of members, when called for. In addition to the regular weekly issues, an extra edition of 20,000 copies was printed in April, 1888, and distributed as sample copies to members of the profession not previously receiving THE JOURNAL, which made the total number of copies of THE JOURNAL circulated during the year 275,000.

*Receipts.*—As all membership dues are paid to the Treasurer of the Association, only the money paid for subscriptions, advertisements, reprints, extra journals, etc., is received at the office of publication. From the sources just named there has been received at this office during the year ending March 31, 1889: From subscribers, \$2,182.53; from advertisements, \$9,731.60; for reprints, \$844.37; from sale of extra Journals, Codes of Ethics, and Volumes of Transactions, \$77.75; for rent of part of printing office, \$150; and for bindery work for outside parties, \$1,317.71; making a total of \$14,303.96, all of which has been paid to the Treasurer of the Association direct, or through the Treasurer of your Board.

*Publication Expenses.*—The total publication expenses for the year ending March 31, 1889, for office rent, materials and labor in printing office and bindery, are \$19,808.65; from which should be deducted \$1,317.71 cash received for work done in the bindery for outside parties, and \$150 for storage use of part of printing office, leaving the actual publication expenses of THE JOURNAL for this year, \$18,340.94.

Under the head of *Editorial Expenses* are included the salary of the Editor, payments for Foreign and Domestic Correspondence, the Reports of Medical Societies, Lectures and Papers, and for Assistant Editorial work. The total amount drawn from the Treasury on account of these items during the year ending March 31, 1889, is \$4,534.38; of which \$1,500 was paid to the Editor for the first nine months of the year, \$333.33 for the month of January, 1889, and the remaining \$2,701.05 for the other items named. It is thus seen that the total current expenses on

account of THE JOURNAL, both publication and editorial, for the year ending March 31, 1889, are \$22,875.32.

*Expenditures on Account of Plant and Fixtures.*—In accordance with the recommendation contained in my report for 1888, which were sanctioned by your Board, \$720.33 was paid for new type, which enabled us to commence Volume XI, July 1, 1888, with an entire new typographical dress and a better quality of paper. To facilitate the work and economize the cost of folding, stitching, wrapping, etc., \$500 was paid for a wire stitching machine to complete the bindery part of the office.

*Property on hand.*—The present property belonging to the Publication Department may be stated as follows:

Printing office, type, fixtures, etc. . . . .	\$1,477.94
Bindery . . . . .	650.21
Business office—safes and furniture . . . .	185.75
	<hr/>
	\$2,313.90

There are stored in the printing office, at the request of the Treasurer of the Association, 1,149 volumes of the Annual Transactions of the Association, issued during the years prior to the establishment of THE JOURNAL, of estimated value \$2,870. About 25 copies of volumes five and six, 75 copies of volumes seven and eight, and 150 copies of volume nine, ten and eleven of THE JOURNAL remain on hand, and 3,000 copies of a cheap edition of the Code of Ethics.

COMPARATIVE TABLE

*Showing the Relative Quantity of Reading Matter in the Five Leading Weekly Medical Journals of the United States:*

NAME.	AVERAGE NO. OF WORDS.		LESS WORDS THAN THE JOURNAL IN 52 ISSUES.	
	In 52 Issues.	In each Issue.	In 52 Issues.	In each Issue.
The Boston Medical and Surgical Journal.	24	1,148	1,308,172	429,728
The Medical News of Philadelphia . . . .	28	1,456	1,410,656	387,244
The Medical Record of New York. . . . .	28	1,456	1,697,280	100,620
The New York Medical Journal . . . . .	28	1,456	1,712,328	85,072
THE JOURNAL. . . . .	36	1,872	1,797,900	

The present status of *THE JOURNAL* in regard to the number of its pages, exclusive of advertisements, and the actual amount of reading matter, in comparison with the four principal weekly medical journals published in this country, is well shown in the foregoing table, prepared by Mr. J. Harrison White, the business manager of our printing and publication office.

A special edition of *THE JOURNAL*, of 75,000 copies, was issued in May, and one addressed to every physician in the United States and Canada. The expense of this edition was fully covered by the receipts from the advertisements obtained for this special number, and left a slight balance in the treasury. The good result of this enterprise is already apparent at the office of publication.

At the beginning of the year the number of pages of *THE JOURNAL* was increased from 32 to 36. This of course carried with it a considerable increase of expense, but we are glad to be able to state that we will close the year free from debt, and are now in possession of a better plant for producing an acceptable journal than at any former period.

All of which is respectfully submitted by the Board of Trustees.

J. M. TONER,  
P. O. HOOPER, W. T. BRIGGS,  
LEARTUS CONNOR, JNO. H. HOLLISTER,  
E. M. MOORE, A. GARCELON.

On motion the report was adopted.

The Permanent Secretary read the following from the American Social Science Association:

*Resolved*, That a committee of three be appointed by the President of this Association, to draw up a suitable resolution, indicative of the sense of this body, upon the necessity of a rigid demand on the part of our medical institutions for a more thorough general education antecedent to the study of medicine; suggesting the adoption of entrance examinations for those candidates not possessing a collegiate or university degree, and furthermore urging our medical colleges so to extend the course of study and increase their facilities that the standard of scholarship may be on a par with like institutions abroad.

*Resolved*, That the same committee draw a resolution which may be presented to the legislative bodies of the respective States, urging the necessity of formulating more stringent laws to guard against the further incorporation of bodies unqualified to properly teach the science of medicine, and to take such steps that all the incorporated medical colleges be subject to a State supervision as to their methods and the standard of instruction.

*Resolved*, That a copy of these resolutions be presented to the American Medical Association.

On motion of Dr. F. Woodbury the communication was accepted.

Dr. P. S. Conner, Ohio, read the Address in Surgery (see page 15).

On motion of Dr. Brodie thanks were offered Dr. Conner for his address, and it was referred for publication.

The Permanent Secretary read the

#### REPORT OF THE TREASURER.

I have the honor to report, as Treasurer, that

there is a balance in the Treasury of the Association at this date of \$2,845.65, as shown by the itemized statement which will accompany this report, and be published at length in *THE JOURNAL* of the Association for the information of members.

There is nothing of special interest to report at this time in connection with the financial relations of the Association, except the statement, which must forcibly address itself to all who have at heart the onward progress of the Association, that the Treasury has never yet, since the establishment of *THE JOURNAL*; or, indeed, at any time during the twelve years in which I have had the honor to occupy the position of Treasurer, failed to respond to all authorized and legitimate demands upon it for the interest and advancement of the Association and the maintenance of its now well established journal.

All of which is respectfully submitted.

RICHARD J. DUNGLISON, Treasurer.

DR. RICHARD J. DUNGLISON, Treasurer, in account with the American Medical Association:

This certifies that we have examined the accounts and vouchers of R. J. Dunglison, Treasurer American Medical Association, for the year ending June 24, 1889, and find them correctly cast and properly vouched.

ALONZO GARCELON,  
W. T. BRIGGS,  
Auditing Committee.

Newport, June 26, 1889.

Also the report of the Auditors.

The undersigned, Auditing Committee of the American Medical Association, beg leave to report that they have attended to the duty devolving upon them and, after close inspection of the bills for the publication of THE JOURNAL of the Association and other expenses pertaining thereto, find that there has been paid into the Treasury of the Association during the year ending June 26, current, the sum of \$33,798.64, and that there has been expended the sum of \$30,952.99, leaving an unexpended balance of \$2,845.65, and that for these expenditures the Treasurer holds bills duly authorized and receipted.

ALONZO GARCELON,  
W. T. BRIGGS,  
Com. for Auditing Accounts.

On motion these were accepted.

The venerable George Bancroft, the historian, having entered on the stage, he was presented to the members, who arose to receive him.

Dr. P. O. Hooper, from the Committee on Nominations, read the following:

#### REPORT OF THE COMMITTEE ON NOMINATIONS.

*To the President and Members of the American Medical Association:*

Your Committee on Nominations have the honor to report that they met yesterday and organized by the selection of Dr. P. O. Hooper, of Arkansas, as Chairman, and Dr. Henry D. Holton, of Vermont, as Secretary. After mature deliberation, they by ballot proceeded to the nomination of the following officers for the ensuing year:

For President—E. M. Moore, of New York.

First Vice-President—J. W. Jackson, of Missouri.

Second Vice-President—H. H. Kimball, of Minnesota.

Third Vice-President—J. H. Warren, of Massachusetts.

Fourth Vice-President—T. B. Evans, of Maryland.

Treasurer—Richard J. Dunglison, of Pennsylvania.

Permanent Secretary—William B. Atkinson, of Pennsylvania.

Librarian—C. H. A. Kleinschmidt, of District of Columbia.

To fill vacancies in Judicial Council caused by expiration of their terms of office—N. S. Davis, Illinois; H. Brown, Kentucky; Wm. Brodie, Michigan; R. C. Moore, Nebraska; G. B. Gillespie, Tennessee; T. A. Foster, Maine; J. B. S. Holmes, Georgia.

To fill vacancies in Board of Trustees of JOURNAL—P. O. Hooper, Arkansas; Alonzo Garcelon, Maine; Isaac N. Love, Missouri. For the unexpired term of E. M. Moore—W. W. Dawson, Ohio.

To deliver the Address on *General Medicine*—N. S. Davis, Illinois.

To deliver the Address on *General Surgery*—Hunter McGuire, Virginia.

To deliver the Address on *State Medicine*—Alfred L. Carroll, New York.

*For Members of the Committee on State Medicine*—Alabama, Jerome Cochrane; Arkansas, Edwin Bentley; California, G. G. Tyrrell; Colorado, J. Wood; Connecticut, J. C. Kenny; Dakota, F. P. Kenyon; District of Columbia, D. W. Prentiss; Delaware, L. Bush; Florida, J. Y. Porter; Georgia, J. P. Logan; Illinois, J. H. Rauch; Indiana, F. W. Beard; Iowa, A. B. Bowen; Kansas, W. L. Schenck; Kentucky, J. N. McCormack; Louisiana, J. J. Bland; Maine, T. J. Foster; Maryland, T. A. Ashby; Massachusetts, H. P. Walcott; Michigan, H. B. Baker; Mississippi, Wirt Johnson; Missouri, H. H. Mudd; Minnesota, Perry H. Millard; North Carolina, T. F. Wood; Nebraska, J. O. Carter; New Jersey, I. N. Quimby; New York, T. M. Flandrau; New Hampshire, D. S. Adams; Ohio, C. G. Comegys; Oregon, W. D. Baker; Pennsylvania, W. T. Bishop; Rhode Island, H. R. Storer; New Mexico, F. H. Atkins; South Carolina, H. T. Horlbeck; Tennessee, J. Berrien Lindsley; Texas, J. Sears; Vermont, D. F. Rugg; W. Virginia, G. W. Baird; Virginia, — Ashton; Wisconsin, J. T. Reeve; Utah, F. S. Bascomb; U. S. Navy, W. D. Wolverton; U. S. Army, F. C. Ainsworth; U. S. Marine-Hosp. Service, J. A. Kinyoun.

*Committee on Necrology*—Alabama, G. E. Ketchum; Arkansas, L. P. Gibson; California, R. H. Plummer; Dakota, F. M. Crain; Connecticut, W. G. Brownson; District of Columbia, A. N. Acker; Florida, Neal Mitchell; Georgia, P. R. Courtleroy; Illinois, D. W. Graham; Indiana, J. F. Hubbard; Iowa, J. B. Ingals; Kansas, Chas. Gardner; Kentucky, H. M. Skillman; Louisiana, J. R. Matas; Maine, A. J. Fuller; Maryland, F. S. Latimer; Massachusetts, G. M. Garland; Michigan, G. E. Ranney; Mississippi, — Trimble; Missouri, J. E. Keft; Minnesota, W. W. Mayo; New Mexico, W. R. Tipton; Nebraska, — Galbreth; New Jersey, J. D. Hough; New York, John W. Brown; New Hampshire, J. W.

Parsons; Ohio, S. P. Deahofer; Oregon, — Shackelford; Pennsylvania, J. B. Walker; Tennessee, J. B. Murphy; Texas, W. Park; Vermont, E. R. Campbell; Virginia, M. L. James; W. Virginia, W. L. Wilson; Wisconsin, — Mackie; U. S. Navy, W. T. Hord; U. S. Army, J. R. Smith; U. S. Marine-Hosp. Service, Fairfax Irwin.

*Committee to appoint Alternates in case any Vacancies occur in the Number selected to give a General Address*—Wm. Brodie, J. H. Murphy, J. T. Morris.

Your Committee name as the place of next meeting Nashville, Tenn., and the time of meeting as the third Tuesday of May, 1890.

Chairman of Committee of Arrangements—W. T. Briggs.

Assistant Secretary—G. C. Savage, Nashville.

(Signed) P. O. HOOPER, Pres.

HENRY D. HOLTON, Sec.

On motion, the report was unanimously adopted and these officers were elected for 1890.

Dr. Culbertson, from the special committee on transportation of members to the sessions of the Association, reported a resolution making it the duty of the Permanent Secretary to secure from all railroads or other means of travel the lowest passenger rates for the sessions of the Association.

After discussion this was adopted.

On motion of Dr. Frank Woodbury the following preambles and resolution were unanimously adopted:

WHEREAS, It is of the utmost importance that the people of this country should enjoy the same advantages from the advances in materia medica, chemistry and pharmacy that are possessed by the people of Europe and other favored nations, and

WHEREAS, The patent laws of the United States appear to be so construed as to protect the foreign manufacturers and purveyors of chemical products, and to discriminate against domestic manufacturers by creating monopolies in the supply of certain new and valuable drugs; therefore be it

*Resolved*, That the American Medical Association hereby most respectfully petitions the Congress of the United States to instruct the appropriate committees to investigate this subject, to take testimony of any such discrimination, to compare the legislation on this subject of the leading Governments of Europe and the practical working of our own laws upon copyright, trade-mark, and any other protection afforded to foreign manufacturers of drugs in frequent use or to be used in the treatment of the sick, and to report such action as it may deem advisable to correct any abuses or injustice to American citizens, if they find such abuse or injustice really exists.

The following was offered by the Section on Ophthalmology:

*Resolved*, That the Ophthalmological Section respectfully desires the Association to authorize this Section to use what influence it can command to induce the Census Committee of the United States for 1890 to extend the tables relative to the blind and to tabulate to the greatest extent possible the causes of blindness.

On motion this was adopted.

The Section on State Medicine offered the following:

This Section has adopted the following Report of the Committee on Uniform Medical Legislation in the United States, and recommend that it be adopted, and that the Secretary of the Association transmit a copy of the Report to the Secretary of each State Medical Society, with the recommendation that each Society exert itself to secure the enactment of a law embodying the provisions of the Report.

*Gentlemen of the Section on State Medicine:*

Your Committee on Uniform Legislation have the honor to submit the following:

That, in our judgment, the best interests of the public will be subserved by the enactment of efficient medical legislation in every State in the Union.

That for the convenience of the profession and the stimulating effect on medical education in this country it is advisable to secure uniformity of legislation in the essential features of all Medical Practice Acts.

This Committee, therefore, begs to recommend as follows—that in future medical legislation the essential features of the enactment be as follows:

That all persons commencing the practice of medicine in any of its branches shall possess a license from the State Board of Medical Examiners.

That all candidates for a license shall submit satisfactory documentary evidence that he or she is a graduate in medicine of a medical institution in good standing with the said Board and having a curriculum possessing at least the following requirements:

*First*.—An entrance examination to test the student's fitness to become a practitioner. This examination shall include at least an examination in English grammar, composition, geography, history, arithmetic, algebra, physics, and the natural sciences; together with at least one of the following languages: Latin, French, or German, provided, however, that graduates of reputable colleges may be exempt from said examination.

*Second*.—Before granting a degree of M.D. or M.B., candidates for same shall have attended at least three full and regular courses of medicine of not less than six months' duration each.

All candidates for a license shall undergo an examination by the said Board of Medical Examiners upon the branches usually taught in medical colleges. Said examination shall be both scientific and practical, but of sufficient severity to test the candidate's fitness to practice medicine and surgery.

Said Board of Medical Examiners shall issue a license to only such persons undergoing an examination as may be deemed suitable persons to practice medicine. Said Board may refuse or revoke a license for the following named causes, to-wit: chronic and persistent inebriety, criminal abortion, or gross unprofessional conduct.

All licenses shall be recorded and made a matter of public record with the County Clerk, or Clerk of District Court, in the county wherein resides said person.

Said Board of Medical Examiners shall be appointed by the Governor, for a period not exceeding five years, the members thereof to be chosen from among the reputable practitioners of medicine of the State of not less than five years' residence.

On motion, the report was adopted.

The same Section offered the following :

It is recommended by the Section on State Medicine that the Committee on Collective Investigation of Disease, at present included in the Standing Committee on Meteorology, be discharged, and that the Committee on Meteorology be continued, with the direction to report to the Section on State Medicine at the next annual meeting of the Association.

On motion, this was adopted.

Dr. Frank Woodbury offered the following, which, on motion, was adopted :

WHEREAS, The American Pharmaceutical Association has appointed a Committee of Conference and sent a delegation to this Association,

*Resolved*, That this Association extends a cordial greeting to the representatives of the American Pharmaceutical Association, and invites them to a seat upon the platform, and

*Resolved*, That a Committee of Conference be appointed to meet the Committee of the American Pharmaceutical Association, for the consideration of subjects of mutual interest and benefit.

*Resolved*, That this Committee report on the second day of the next annual meeting of this Association the result of their conference, with such recommendations as they may deem advisable in the premises.

The Permanent Secretary read the following :

Your Committee on Dietetics beg leave to report : The special topic referred for investigation has been entertained and partially discussed at this session, but not so fully as to warrant a report at this time that will completely satisfy all the requirements of the subject. We therefore report progress and ask that the Committee be continued.

(Signed) E. A. Wood, Chairman.

The report was received and the Committee were continued.

Dr. A. L. Gihon offered the following amendment to the By-laws :

That the first day of the meeting of this Association shall be on the first Wednesday of May or June, respectively, instead of Tuesday.

Laid over until next meeting.

The Section on Practice of Medicine offered a resolution, that the President appoint three delegates to attend the Convention to revise the Pharmacopœia, which meets in May, 1890. This was adopted.

The Association adjourned until Friday at 10 A.M.

FOURTH DAY, JUNE 28.

The President called the Association to order at 10 A.M.

Prayer was made by Rev. D. A. Jordan.

Dr. Storer in making the final announcements, took occasion to thank the Association for the many kindnesses they had shown the committee.

The Permanent Secretary read the report of the Librarian, which will appear in a future issue, with a recommendation that the usual appropriation of \$10 be made for the *Index Medicus*.

On motion of Dr. Davis the report was accepted and the appropriation was made.

The Address on State Medicine was then delivered by Dr. W. H. Welch, of Maryland. (See page 73.)

On motion of Dr. J. B. Hamilton the address was referred for publication, with thanks to the author for his very able, instructive and entertaining paper.

The President appointed as the committee to confer with the Social Science Association Drs. C. G. Comegys, Ohio ; J. B. Hamilton, U. S. Marine-Hospital Service, and A. M. Owen, Maryland.

By request of the Section on State Medicine the Committee on Fœticide was discharged.

The President appointed as the committee to confer with the American Pharmaceutical Association : Drs. G. E. Frothingham, Mich. ; J. C. Culbertson, Ohio ; Frank Woodbury, Pa. ; Isaac N. Love, Mo. ; F. C. Shattuck, Mass.

As the delegates to the Convention for revision of the Pharmacopœia : Drs. H. A. Hare, Pa. ; N. S. Davis, Jr., Ill. ; Elmer Lee, Mo.

Dr. X. C. Scott, Ohio, offered an amendment to the By-laws abolishing the Committee on State Medicine inasmuch as the Section on State Medicine occupies the entire ground.

This will lie over till next year.

On motion of Dr. N. S. Davis, the President was requested to appoint a committee to take charge of the procuring excursion rates, and to select the most feasible route to the Tenth International Medical Congress in Berlin. Committee : Drs. W. H. Pancoast, Pa., J. B. Hamilton, D. C., A. N. Bell, N. Y., A. H. Beidler, Md. ; N. S. Davis, Ill.

The Permanent Secretary read the following names as appointed to attend the British Medical Association in Europe during 1889 : Drs. A. J. Fuller, Me. ; E. Cutter, N. Y. ; P. O. Hooper, Ark. ; J. H. Knight, Ct. ; I. N. Love, Mo. ; J. M. Mathews, Ky. ; W. C. Wile, Ct. ; W. F. Hutchinson, R. I. ; A. N. Owen, Ind. ; I. N. Quimby, N. J. ; J. W. Jackson, Mo. ; F. J. Lutz, Mo. ; S. E. Solly, Col. ; J. F. Noyes, Mich. ; J. M. French, Ohio ; A. Segur, N. Y. ; D. A. Hengst, Pa. ; J. Taber Johnson, D. C. ; R. H. Plummer, Cal.

To the Canadian Medical Association, Dr. P. S. Conner, Ohio.

To the International Medical Congress to be held in Berlin in 1890: Drs. J. B. Hamilton, D. C.; J. F. Noyes, Mich.; F. Woodbury, Pa.; W. W. Keen, Pa.; A. J. Fuller, Me.; E. Cutter, N. Y.; N. C. Scott, Ohio; W. H. Pancoast, Pa.; W. F. Waugh, Pa.; E. H. M. Sell, Pa.; J. Taber Johnson, D. C.; J. M. French, Ohio; N. S. Davis, Ill.; A. P. Clarke, Mass.; Chas. S. Wood, N. Y.; A. H. Wilson, Mass.; James Collins, Pa.; R. H. Plummer, Cal.

On motion of Dr. J. B. Hamilton, it was resolved that the American Medical Association hereby expresses its profound sympathy with the unfortunate citizens of the city of Johnstown, Pa. and vicinity, and especially with the members of our profession therein residing, and that as a mark of our sympathy the treasurer be instructed to remit the dues for the ensuing year of any member of this Association living in said place.

Dr. J. M. Toner submitted his report as Chairman of the Committee on Necrology.

#### OFFICERS OF SECTIONS.

The Sections reported their officers as follows: *Practice of Medicine, etc.*—J. H. Musser, Pa., Chairman; H. McColl, Mich., Secretary.

*Surgery and Anatomy.*—B. A. Watson, N. J., Chairman; J. B. Deaver, Pa., Secretary.

*Obstetrics and Diseases of Women.*—W. W. Potter, N. Y., Chairman; J. Hoffman, Pa., Secretary.

*State Medicine.*—John B. Hamilton, D. C., Chairman; F. S. Bascum, Utah, Secretary.

*Ophthalmology.*—S. C. Ayres, Ohio, Chairman; E. J. Gardner, Ill., Secretary.

*Laryngology and Otology.*—John O. Roe, N. Y., Chairman; Frank H. Potter, N. Y., Secretary.

*Diseases of Children.*—Isaac N. Love, Mo., Chairman; E. F. Brush, N. Y., Secretary.

*Medical Jurisprudence.*—T. B. Evans, Md., Chairman; L. Crothers, Ct., Secretary.

*Dermatology and Syphilography.*—I. E. Atkinson, Md., Chairman; W. T. Corlett, Ohio, Secretary.

*Oral and Dental Surgery.*—J. L. Williams, Mass., Chairman; E. S. Talbot, Ill., Secretary.

W. B. ATKINSON, M.D., Secretary.

*Dear Sir:*—It is with great regret that I am compelled to decline the office of Chairman to the Section of Dermatology and Syphilography to which I have been elected. Deeply grateful for the high honor paid me by the Section, I remain, your very obedient servant.

June 27, 1889.

I. E. ATKINSON.

Several Sections reported their minutes and papers, which were referred to the Trustees for publication.

On motion of Dr. W. L. Schenck, it was

*Resolved*, That the thanks of the Association are tendered to Dr. H. R. Storer, Chairman, and the members of the Committee of Arrangements; to the Profession of Newport and of Rhode Island for the courtesies so liberally extended during the session; to His Honor, Mayor Thomas Coggeshall, and the City Council; to Rev. Dr.

Thayer, Right Rev. Bishop Clark, Rev. Jas. Coyle, and Rev. D. A. Jordan; the Trustees of the Newport Hospital; the Newport Historical Society; the Redwood Library; the People's Library; the Rev. Rabbi Mendes; the Trustees of the Chauncy Memorial Church; Mr. H. Bull, Jr., for the use of the Opera House; the Business Men's Association; Capt. J. Waters, Asst. Sup't Third Life Saving Station; Commander C. F. Goodrich, U. S. Navy; Commander F. J. Higginson, U. S. Navy; Col. John Mendenhall, U. S. Army; to His Excellency, Herbert W. Ladd, Governor of Rhode Island; the Rhode Island Medical Society; Hon. Geo. Bancroft, who gave 400 roses for every lady accompanying the delegates; the Medical Faculty of Harvard University; and to Lewis Brown, the Postmaster of Newport.

Dr. W. H. Pancoast offered a vote of thanks to Sir James Grant, M.D., of Canada, for his admirable address and desire to express our pleasure in having him with us. We will always welcome cordially our British Medical brethren.

This was carried by a rising vote.

Sir James Grant replied to the sentiment.

The President elect having been called away, his installation was necessarily postponed.

President Dawson then arose and declared the Association adjourned to meet in Nashville, the third Tuesday in May, 1890.

W. B. ATKINSON,

Permanent Secretary.

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*Dr. Jacobi reads some Notes on the Baking of Bacilli, at the Academy of Medicine—Dr. John C. Peters reports for the Committee on Croton Water Nuisances—Mr. R. H. Robertson exhibits and describes the plans of the New Academy Building—Commencement Exercises at the College of Physicians and Surgeons—The Presidency of the Board of Health—The Election of Dr. E. M. Moore, of Rochester, N. Y., as President of the American Medical Association, received with enthusiasm.*

It was not expected that there would be any scientific exercises at the last meeting of the Academy of Medicine before the summer vacation, but on account of special circumstances and the importance of the subject, Dr. Jacobi was given the privilege of reading some "Notes on the Baking of Bacilli." It will perhaps be remembered, in this connection, that a few months ago Dr. Louis Weigert's hot air inhalation apparatus was exhibited at a meeting of the Section on Practice of the Academy, and a very rose-colored account given of the wonders accomplished by it. Having stated that of late the inhalation of dry hot air in pulmonary tuberculosis had attracted considerable attention, Dr. Jacobi made some remarks strongly condemnatory of all pat-

ented apparatuses and processes in medicine; and then went on to say that Weigert's apparatus, which has been patented, was quite imperfect in its mechanical construction and, in addition to its other objections, was sold at a very high price.

He stated that the attention of the profession was first directed to the use of dry hot air in phthisis by Dr. Louis Halter, in an article published in two numbers of the *Berliner Klinische Wochenschrift* in September, 1888, and accompanied by a representation of an apparatus which he had devised. Halter's attention was first drawn to the matter by the exemption of lime-kiln workers from tuberculosis, and his observations, extending over a period of fifteen years, were made in Westphalia, where this disease was very prevalent among the general population. The air about the ovens is quite dry and very hot, the thermometer usually ranging from  $122^{\circ}$  to  $158^{\circ}$  F. Such air must, therefore, be for the most part free from tubercle bacilli, which, as is well known, perish at a temperature of from  $140^{\circ}$  to  $149^{\circ}$  F. The air about the lime-kilns is also greatly rarefied, and it has the effect in the case of newcomers of increasing the body temperature  $2.5^{\circ}$  above the normal, while the pulse is raised to 120 to 160, and the respiration to 20 to 80. Old hands, however, perspire very freely, and feel perfectly well.

Another paper on the inhalation of dry hot air in phthisis was also published in the *Berliner Klinische Wochenschrift* in September, 1888, by Dr. E. Krull, and this was also accompanied by a representation of an apparatus devised by the author. It was not until December of the same year that Dr. Louis Weigert published an account of his apparatus in the *New York Medical Record*, and in his communication he made no mention whatever of the articles of Drs. Halter and Krull. About the same time he also exploited his apparatus in the public press, proclaiming himself worthy to be considered the equal of Koch by reason of his great invention, by means of which consumption was entirely curable.

Dr. Jacobi then went on to say that he had experimented with the Weigert apparatus to a considerable extent in his wards at Bellevue Hospital, and that the results had not been at all satisfactory. It was true that, in many of the cases, more or less improvement was noted while it was being used; but it was a well established fact that every patient coming to the hospital with phthisis, except the disease is in its last stages, improves for a time after entrance, on account of the nutritious diet, rest, freedom from care, etc. He found by repeated observations that the temperature of the air to be inhaled from the apparatus was always many degrees cooler by the time it had passed through the tube conveying it to the mouth of the patient than it was when it left the cylinder where it was heated. In addition, the temperature of the air was further reduced in the

pharynx and trachea, and when the proportionately small amount remaining finally reached the great volume of the blood and was diffused over the extended surface of the lungs, it was still more cooled down. In fact, the expired air was warmer than the inspired air. When it was remembered, furthermore, that the bacilli were located and multiplied deep in the tissues, it seemed hardly probable that they were disturbed at all; and it was not even likely that the soft lung tissue could be heated above normal, while neither the pulse or the general temperature of the body showed any alteration. It was evident, therefore, that in order to destroy the bacilli something more was required than the inhalation of hot air in an ordinary room. The temperature of the apartment in which the inhalations were given ought to be at least  $108^{\circ}$ . The men working at the lime-kilns mentioned by Halter were subjected to a temperature varying from  $106^{\circ}$  to  $158^{\circ}$ .

Both the hot inhalations and the hot room, Dr. Jacobi said in conclusion, would find their contraindications in all cases where the patients were weak or liable to hæmoptysis, and could only be employed with safety, therefore, where the patient was comparatively robust. He believed, consequently, that this method of treatment should be resorted to only in the very earliest stage of phthisis. In the cases in which he had used the hot inhalations, other causes, as he had mentioned, would account for the improvement where any improvement was noted. In a few he found it difficult to control the cough excited by the treatment, and in two instances it caused so much vomiting, with other disagreeable symptoms, that the patients were decidedly relieved by the discontinuance of the inhalations.

Dr. John C. Peters, chairman of a committee appointed at the last meeting in regard to Croton water nuisances, reported that the committee had made an earnest appeal to the Department of Public Works, which, it seems, is legally responsible in the matter, for the prompt suppression of all nuisances existing along the Croton watershed. The inhabitants of a considerable part of three counties are apparently constantly engaged in polluting the water-supply of New York, and attention has been emphatically directed to the abuse in the report published by the State Board of Health last winter; a thorough investigation having been made during the latter part of last year, in response to an application by Mayor Hewitt to this Board.

A similar investigation was made in behalf of the City Board of Health in 1884. There was much discussion at that time as to what should be done about the matter, and legislation has since been obtained to enable the public authorities to put a stop to the nuisances. It was not reassuring to find, when the result of the investigation of the State Board of Health was pub-

lished, that the nuisance was not only unabated, but had gone on steadily increasing with the growth of villages, the multiplication of summer resorts, and the increase in industries in the valleys of the Croton district. Where Mr. Lucas, who made the former investigation, found 1,879 houses draining into the streams which fed the Croton in 1884, Mr. Brown, the engineer for the State Board of Health, found 2,843 in 1888. Barns and barnyards have also multiplied, and the refuse of a growing population and an increasing number of domestic animals, together with the foul waste of mills and factories, is poured into the Croton water in a constantly swelling volume.

The State Board of Health followed its investigation by formulating "Rules and Regulations for the Sanitary Protection of the Croton River and its Tributaries," but as it had no legal authority to enforce these rules, nothing whatever has been done about the abatement of the nuisance. A determined effort is therefore to be made to induce the Commissioner of Public Works, who alone, under the existing laws, has the power to do so, to take such action as will remove the present sources of pollution and keep the water-supply pure in the future.

On this occasion Mr. R. H. Robertson, the architect, who, by the way, is a son-in-law of Prof. T. M. Markoe, exhibited and described the plans of the new Academy building, which is to occupy a lot 75 feet wide and 100 feet in depth on Forty-third St., near Fifth Avenue. It will be five stories in height, with a gable story, and is to be constructed of brick and a handsome reddish-brown stone known as Longmeadow stone. On the first floor in front are to be a smoking-room 36 by 26 feet and other smaller rooms, and in the rear the large assembly room, 57 by 42 feet, and a handsome dining-room, 31 by 26 feet. These two rooms will be separated by a rolling partition, so that they can be thrown into one at any time when required for large meetings or a largely attended dinner. One and a half stories will be taken up by this part of the building, and the rooms will be 26 feet in height. The half-story in front, 11 feet in height, is to be used for committee-rooms, etc. On the next floor will be the reference library and the stack-room, occupying a story and a half, with three reading-rooms, of less height, in front. The full capacity of the stack-room will be for 230,000 volumes, to accommodate which there will eventually be three tiers of stacks. At first, however, but a single tier will be required by the library. The next floor will be taken up by four section rooms, each with an anteroom and specimen or apparatus room, and accommodating respectively 160, 225, 225 and 110 persons. In the top story, which will not extend over the entire area of the building, will be a microscope room and librarian's apart-

ments, and the rest of the space will be devoted to an open deck, which will probably be fitted up as a summer garden. After the meeting there was a social reunion, with a collation, and the loving cup was passed merrily around.

At the recent Commencement of the College of Physicians and Surgeons the graduating class numbered 166, the largest in the history of the College. Professor James W. McLane, through whose instrumentality the munificent gifts of the Vanderbilts to the institution were mainly secured, has been selected for the Presidency, made vacant by the death of the lamented Dalton, and Prof. T. M. Markoe appointed Vice-President of the College.

Much indignation was felt by the profession at the appointment by Mayor Grant, a short time since, to the Presidency of the Board of Health, of Mr. Charles G. Wilson, a man without experience and, so far as known, utterly without knowledge in sanitary matters, in the place of Mr. Bayles, an expert, and one who has filled the duties of the position in the most admirable manner. This feeling found voice in a resolution introduced at a recent meeting of the Academy of Medicine by Dr. Walter Mendelson, to the effect that, in the opinion of the Academy, the appointment to the Presidency of the Board of Health of any one not specially qualified is fraught with possibilities of the gravest danger to the public health; and furthermore, that the Academy, having at heart the public good, urges the Mayor to reconsider the appointment and, after due consultation with those acquainted with the duties of the office, make a new appointment better suited to the important nature of the department.

In the preamble it is set forth that the Board of Health is a department of the City Government in which every member of the community is most personally and vitally interested, and one where it is absolutely necessary for true efficiency that the presiding officer be acquainted with sanitary science and have a knowledge of the laws of health and of disease; that the medical profession, as guardian of the health of the community, is being brought into daily contact with the workings of the Board of Health, and therefore especially interested in its efficiency; and that the Mayor of the City of New York has appointed to the Presidency of the Board one whose previous experience nowise justifies the belief that he is at all fitted to assume the grave responsibilities of the office intrusted to him.

It was deemed best before submitting the resolution to the vote of the Academy, that it should be referred to the Council for mature consideration, and therefore no definite action will probably be taken in the matter before autumn. There is, however, a growing feeling that the possibility of the appointment of an utterly incompetent President of the Health Department of a city like New

York is an outrage upon the community, and it is probable that urgent efforts will be made to induce the next Legislature to amend the present law in such a way that no one can be appointed to this position who is not a doctor of medicine or an expert in sanitary science. As the law now stands, strangely enough, no physician is eligible to the Presidency, and the great medical profession of New York is entitled to but one representative as Commissioner in the Board of Health; so that our medical men feel that it is time that they should claim some right to proper recognition in a body with which their profession has so much to do and with the interests of which it is so closely identified.

The election of Dr. E. M. Moore, of Rochester, as President of the American Medical Association meets with much enthusiasm here, and, aside from the fact that nowhere in the profession could there be found one more eminently qualified by natural gifts and special culture to fill the position with dignity and grace, it is felt that the selection is in some sense a recognition of the loyalty of that portion of the New York profession which has always stood true to the National colors, and of which Professor Moore is one of the most distinguished ornaments. In this connection it may be stated that the continued prosperity of our State Association, of which Dr. Moore was the second President, is sufficiently attested by the last excellent volume of Transactions, recently issued under the admirable editorship of Dr. Carroll; while the New York County Medical Association has never been so flourishing as at present, about a hundred new members, including many prominent physicians, having been added within the last four months.

P. B. P.

## MISCELLANY.

### DR. JOHN S. BILLINGS AND THE ELEVENTH CENSUS.

—Through an oversight the following circular to the profession, issued by the Superintendent of the Eleventh Census, was omitted at the proper date. The attention of our readers is especially directed to the instructions contained therein: "The various medical associations and the medical profession will be glad to learn that Dr. John S. Billings, Surgeon U. S. Army, has consented to take charge of the Report on the Mortality and Vital Statistics of the United States as returned by the eleventh census. As the United States has no system of registration of vital statistics, such as is relied upon by other civilized nations for the purpose of ascertaining the actual movement of population, our census affords the only opportunity of obtaining near an approximate estimate of the birth and death rates of much the larger portion of the country, which is entirely unprovided with any satisfactory system of State and municipal registration. In view of this, the Census Office, during the month of May, this year, will issue to the medical profession throughout the country 'Physicians' Registers' for the purpose of obtaining more accurate returns of deaths than it is possible for the enumerators to make. It is

earnestly hoped that physicians in every part of the country will cooperate with the Census Office in this important work. The record should be kept from June 1, 1889, to May 31, 1890. Nearly 26,000 of these registration books were filled up and returned to the office in 1880, and nearly all of them used for statistical purposes. It is hoped that double this number will be obtained for the eleventh census. Physicians not receiving registers can obtain them by sending their names and addresses to the Census Office, and, with the register, an official envelope which requires no stamp will be provided for their return to Washington. If all medical and surgical practitioners throughout the country will lend their aid, the mortality and vital statistics of the eleventh census will be more comprehensive and complete than they have ever been. Every physician should take a personal pride in having this report as full and accurate as it is possible to make it. It is hereby promised that all information obtained through this source will be held strictly confidential.

ROBERT S. PORTER, Sup't of Census.

**MEDICAL SOCIETY OF VIRGINIA.**—The twentieth annual session of this Society will convene in Roanoke, Va., Tuesday, Sept. 3, 1889, at 8 P.M. Special attention is called to the following resolution adopted 1884:

"*Resolved*, That the Secretary be instructed to send out a notice to each member of the Society two months in advance of the day of meeting calling for the titles of any papers to be read before the Society—said titles to be returned to the Secretary at least five weeks before the day of session—failure in which will relegate any papers to the last day of the session; that the Secretary shall classify such titles according to subjects, and, in publishing his programme, assign all papers on or pertaining to the same classification (such as Surgery, Diseases of Women, etc.) to be read the same day, specifying the day, with a limit of one-half hour to each paper; and fifteen minutes for each discussion, unless this time is extended by a two-thirds vote of those present."

The subject for general discussion is "Croupous Pneumonia," Dr. B. L. Winston, of Hanover C. H., Va., Leader. Parties preparing papers on this subject should notify the Secretary. Circular announcement will be issued about a month hence. Send applications for Fellowship, with name and post-office in full, name of college, and date of graduation in medicine, date of passing examination successfully before Medical Examining Board of Virginia, name of a Fellow who recommends the applicant, and \$2.00 initiation fee, to the Recording Secretary, Landon B. Edwards, M.D., Richmond, Va.

THE MEDICO-LEGAL SOCIETY has issued the following circular:

NEW YORK, JUNE 20, 1889.

*Dear Sir:*—The recent session of the International Congress of Medical Jurisprudence was successful beyond the most sanguine expectations of its promoters. It perfected a permanent organization and provided for the selection of an additional Vice-President from each State and Territory of the American Union, and from each foreign province, State and country who had members in the organization who took an interest in the success of the movement.

Future meetings were authorized to be called by the executive officers, a list of whom is herewith sent you.

The expenses of publishing all the papers read at this Congress, with a record of its transactions and the proceedings at the banquet, will fill a large volume, the expense of which it is estimated will be about \$700. The executive officers were authorized to elect additional members into the organization, the only expense of which is the enrolling fee of \$3, which entitles the members to the Bulletin free.

Will you unite in this movement with a view of making it International, and will you suggest a suitable name for Vice-President from your State, Territory, province

or country. If this effort is received with favor by the members of the Medico-Legal Society, active, corresponding and honorary alone, without counting others, it will at once provide for the publication of the transactions and the papers read before the Congress, and lay on firm and sure foundations the International work of promoting the advancement of medical jurisprudence, not alone in the United States of America, but throughout the civilized world.

Your coopération in this effort is earnestly solicited in your locality, and your name will be laid before the executive officers for enrollment as a member on receipt of the enrolling fee, which can be sent to any officer of the body.

The officers elected by the Congress, held June 4 to 7, 1889, in New York, were as follows: President—Clark Bell, Esq., of New York. Vice-Presidents—Chief Justice Sir John C. Allen, of New Brunswick; Chief Justice Edward F. Bermudez, of Louisiana; Dr. Bettincourt Rodrigues, for Portugal; Gov. Biggs, of Delaware; Dr. Daniel Clark, of Toronto, Canada; Ex-Chief Justice Noah Davis, of New York; Dr. Edward J. Doering, of Illinois; Prof. John J. Elwell, of Ohio; Judge W. H. Francis, of Dakota Ter.; Dr. W. W. Gedding, of Washington, D. C.; Dr. Eugene Grissom, of North Carolina; Dr. Carl H. Horsch, of New Hampshire; Judge Locke E. Houston, of Mississippi; Dr. Charles H. Hughes, of Missouri; Dr. W. W. Ireland, of Scotland; Prof. Robt. C. Kedzie, of Michigan; Dr. Norman Kerr, of England; Dr. Jules Morel, of Belgium; Dr. Jennie McCowen, of Iowa; Dr. Connolly Norman, of Ireland; Prof. John J. Reese, of Pennsylvania; Judge H. M. Somerville, of Alabama; David Stewart, Esq., of Maryland; Theo. H. Tyndale, Esq., of Massachusetts. Secretary—Moritz Ellinger, Esq., of New York. Assistant Secretaries—Dr. Frank H. Ingram, of New York; Dr. Wm. J. Lewis, of Connecticut; J. F. Walters, of New York.

The President was empowered and directed by the Congress to appoint additional Vice-Presidents for the various States, Territories, provinces and countries, which will be done during the summer vacation. Members of the Congress receiving this circular, who have not sent their enrolling fee, will please do so, and circulate this among those who take an interest in the science.

Your early response is requested to either of the undersigned.

CLARK BELL, President,  
MORITZ ELLINGER, 57 Broadway, New York.  
Surrogate's Office, New York City.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—At a meeting of the General Committee, at Newport, it was decided to change the date of meeting of this Association to September 10, 11, and 12, 1889. This promises to be the largest and most interesting meeting in the history of this Association. A large attendance of representative men from all parts of the United States has been assured.

#### LETTERS RECEIVED.

Dr. O. D. Haven, Allegheny, Pa.; Dr. Henry W. Elmer, Bridgeton, N. J.; E. M. DePuy, Washington; Dr. S. L. Holley, Nanticoke, Pa.; Dr. C. Park, Oquaque, Ill.; Dr. F. B. Schulz, Cape Girardeau, Mo.; Jerome Kidder Mfg. Co., New York; Dr. C. A. Harvey, New York; Dr. Richard J. Duglison, Philadelphia; Dr. J. A. Dibrell, Jr., Little Rock, Ark.; Dr. W. N. Miller, Pittsburgh, Pa.; Dr. Charles Disen, Minneapolis, Minn.; Dr. W. VanHook, Chicago; Dr. I. B. Ellis, Bethany, Mo.; Malted Milk Co., Racine, Wis.; Dr. James E. Morgan, Washington; Dr. Wm. C. Dabney, White Sulphur Springs, Ky.; Dr. Joseph Price, Philadelphia; Dr. N. P. Dandridge, Cincinnati, O.; W. L. Minter, Louisville, Ky.; Medical Herald Co., St. Joseph, Mo.; Dr. G. K. Dickinson, Jersey City, N. J.; J. F. Widman, McGregor, Ia.; Dr. J. F. Page, Powersville,

Mo.; Dr. Thos. Cosgrove, Auburndale, O.; Dr. F. G. Albright, Lancaster, Pa.; Dr. W. H. Landis, Woodland, Mich.; Dr. G. W. H. Kemper, Muncie, Ind.; Dr. Horace M. Starkey, Chicago; Dr. J. C. Hoag, Chicago; Galvano Paradié Mfg. Co., New York; Dr. G. R. Wells, Gold Hill, Col.; Dr. A. L. Hummel, Philadelphia; Dr. J. W. Long, Bryan, O.; Dr. J. T. Jelks, Hot Springs, Ark.; Dr. A. P. Brown, Fort Worth, Tex.; Dr. Joseph Eastman, Indianapolis, Ind.; Dr. David Barrow, Lexington, Ky.; Dr. J. B. Murdoch, Pittsburgh, Pa.; G. H. Mitchell & Co., Cedar Rapids, Ia.; Dr. W. T. Lusk, Brooklyn, N. Y.; Dr. A. M. Owen, Evansville, Ind.; Fred. D. Van Horen, New York; Dr. Gersham H. Hill, Independence, Ia.; Dr. H. R. Storer, Newport, R. I.; Dr. Albert F. Stifel, Wheeling, W. Va.; Dr. W. I. Haddens, St. Joseph, Mo.; Publishers' Commercial Union, Chicago; Dr. A. R. Stewart, Toledo, O.; Dr. J. G. Truax, New York; Dr. G. F. Smolt, Nickerson, Kan.; Dr. J. W. Muenich, Jefferson, Wis.

#### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from July 6, 1889, to July 12, 1889.*

By direction of the acting Secretary of War, the retirement from active service this date, by operation of law, of Col. Thomas A. McParlin, Surgeon, under the provisions of the Act of Congress approved June 30, 1882, is announced. Col. McParlin will repair to his home. Par. 2, S. O. 157, A. G. O., July 10, 1889.

Major H. O. Perley, Asst. Surgeon U. S. Army, is ordered to accompany troops from Ft. Wayne, Mich., to Gognac Lake, Mich., to encamp there with the Michigan State troops from August 8 to 13, 1889. Par. 1, S. O. 154, Hdqrs. Div. of the Atlantic, July 9, 1889.

Capt. H. O. Perley, Asst. Surgeon U. S. Army, is granted fourteen days' leave of absence, to commence about July 14, 1889. Par. 2, S. O. 154, Hdqrs. Div. of the Atlantic, July 14, 1889.

Col. Andrew K. Smith, Surgeon U. S. Army, promoted to Surgeon with rank of Colonel, to rank from July 10, 1889. Vice McParlin, retired.

Lient.-Col. Francis L. Town, Surgeon U. S. Army, promoted Surgeon, with rank of Lient-Colonel, to rank from July 10, 1889. Vice A. K. Smith, promoted.

Capt. W. C. Gorgas, Asst. Surgeon, is granted leave of absence for one month, to take effect on the arrival of a medical officer to relieve him. Par. 2, S. O. 84, Hdqrs. Dept. of the Missouri, July 3, 1889.

By direction of the Secretary of War, Capt. Andrew V. Cherbonnier, Medical Storekeeper, will, in addition to his present duties, take charge of the office and perform the duties of acting Assistant Medical Purveyor in St. Louis, Mo., during the absence of Capt. George T. Beall, Medical Storekeeper. Par. 2, S. O. 151, A. G. O., July 2, 1889.

#### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending July 13, 1889.*

Asst. Surgeon S. Stuart White, ordered to the Naval Hospital, Brooklyn, N. Y.

Medical Inspector C. H. White, detached from the "Trenton" and wait orders.

P. A. Surgeon Ernest Norfleet, detached from the "Trenton," and to the "Monocacy."

P. A. Surgeon H. E. Ames, detached from the "Monocacy," proceed home and wait orders.

Surgeon G. E. H. Harmon, detached from the "Constellation" and to the Naval Academy.

Asst. Surgeon C. H. T. Lowndes, detached from the "Constellation" and to the Naval Academy.

Surgeon H. P. Harvey, detached from the "Vandalia" July 7, proceed home and wait orders.

Asst. Surgeon S. Stuart White, detached from the "Trenton" July 7, 1889.

### THE TREATMENT OF SALPINGO-OVARITIS BY ELECTRICITY.

*Being a paper prepared for the Gynecological Section of the American Medical Association Meeting at Newport, June 27, 1889.*

BY GEORGE APOSTOLI, M.D.,  
OF PARIS.

The electrical treatment of fibroma which I originated has made great strides despite the railings of charlatans and incompetent persons; it is not necessary to refer to this subject again, because it is a child that will grow of itself, and is amply able to take care of itself. To-day I invite your attention to a subject of equal interest, I mean the treatment by electricity of salpingo-ovaritis, and I sincerely hope that it may have the same useful future, more restricted perhaps, because at present it is restricted to a certain number of cases, but in any case worthy of your consideration.

Salpingo-ovaritis is a disease which has long been recognized, but under names which I have changed very often: *Phlegmon*, *pelvic-peritonitis*, *lymphangitis*, *adeno-lymphangitis*, *cellulitis*, *peri-metritis*, *para-metritis*, *peri-uterine*, *phlegmasia*, etc.; all of these titles being used to picture a disease originating in the lymphatics, in the cellular tissue, or in the peritoneum, according to the special pathological views of the individual describing the malady. Laparotomy had the advantage of fixing the diagnosis precisely, by demonstrating that lesions of the ovary and of the tube were almost constant factors, and that these inflammations almost always took origin in the lining membrane of the uterus, and from there spread to the adnexa, the cellular tissue, and the peritoneum. At the commencement of my practice I fell into the common pathological error, which I hasten to correct to-day: But one fact is beyond dispute, and that is that the conditions which I then treated as *phlegmon*, and *peri-metritis*, and which concealed a *salpingo-ovaritis*, does not militate in the least against my claim to priority in the electrical handling of the disease under discussion.

Since 1882 I have treated all cases that come to my clinic by electricity, whether suffering from

tumors, from endometritis, or peri-uterine phlegmasia. Look for a moment at the thesis of my assistant, Dr. L. Carlet, which appeared in July, 1884,<sup>1</sup> and which I myself revised thoroughly: "One pole (the negative) is that of *dénutrition par excellence*; it is suitable, therefore, not only for tumors, but for sub-acute peri-uterine inflammations (circumscribed), without fever, which are connected with the uterus, and which considerably disturb its functions." Farther on, you may read with profit the clinical histories of twenty cases<sup>2</sup> of peri-uterine phlegmasia, complicating uterine tumors, which were treated with electricity. I quote as follows, (page 110). "This observation is of the greatest importance, because it shows the value of intra-uterine galvano-caustique in moderate doses, in causing a resolution of sub-acute peri-metritis." Further on I wrote: "This observation (page 117) should be of great importance, since it shows, first, that intra-uterine galvano-caustique, badly done, or made unduly painful, may set up multiple accidents, and here, the peri-uterine phlegmasia is clearly due to the last application. On the other hand, this observation also proves, that hysterometry, badly done, is dangerous, but when well done is never so, even in the sub-acute stage of peri-uterine phlegmasia; this same malady, indeed, has been treated with uterine faradization (that is by another form of hysterometry), during the convalescent stage of a phlegmon of the broad ligament, which resulted in a complete cessation of symptoms after a very short treatment."

From 1884 to 1887, my experience has enlarged coincidently with greater skill, boldness in operating, and at the Dublin Congress (August, 1887), I discussed the question under an entirely new caption. (See *Bulletin général de Thérapeutique*, of September 30, 1887, and *British Medical Journal*, of November 19, 1887). To-day the names have changed, but the ideas are the same, and I propose giving you the results of my electrical treatment. I shall speak no more of *peri-metritis*, but of *salpingo-ovaritis*, whether complicating a pelvic peritonitis or not. The atti-

<sup>1</sup> Du traitement électrique des tumeurs fibreuses de l'utérus d'après la méthode du Dr. Apostoli par le Docteur Lucien Carlet. Paris, Octave Doin, Éditeur, 1884.

<sup>2</sup> See observations (op. cit.) on pages 74, 81, 85, 94, 108, 114, 120, 123, 124, 151, 169, 196, 205, 214, 216, 225, 227, 232, 236, 241.

tude of those doctors who occupy different and opposing ground, is very curious, and may, briefly, be described as follows: the large number, following in the footsteps of a wise ancestry, when confronted with a salpingo-ovaritis, exclaim, "Do not touch it." They ignore all intra-uterine interference, relying upon poultices and revulsives. Their success is variable. The cavity of the uterus is, for them, a *noli me tangere*, which they religiously avoid. Others, on the contrary, comprising a small number of surgeons, anxious of statistical fame, open the abdomen of every woman having an undue sensitiveness of the adnexa, either for exploration or castration. Here the abuse cries out for reform, and if, under some circumstances, the services of the surgeon are indispensable, yet here, one may justly exclaim with indignation, that in many cases, surgery, out of selfishness, consigns a woman to a future of sterility. The true path, gentlemen, lies between the two extremes. If, on the one hand, doctors are over-timid, and count too largely upon nature to cure certain diseases, which almost never, are spontaneously cured, on the other hand, surgeons commit a fault quite as reprehensible, by hasty operations; for we know now that castration sometimes kills, and does not always cure, forgetting that, clinically speaking, these cases are frequently curable by more simple and conservative means, without causing an irreparable physical and moral shock to the woman.

From the very commencement, despite the prejudice from all sides, my treatment of these cases has been absolutely and entirely the intra-uterine electric. This idea, at first theoretic, is to day a fixed fact, thanks to pathological investigation which demonstrates that almost all cases of peri-uterine phlegmasia or salpingo-ovaritis, have their starting point in an endometritis, which is often the posthumous witness of the secondary lesion of propagation, cleanse the uterus, make use of intelligent intra-uterine antiseptics, cure the endometritis, and provoke healthy intra-uterine derivation—such are the general considerations that have guided me on to such results. These are the reasons why, at the very first, I swept away the existing prejudices against an interference with the uterine cavity, and why I went at once to the bottom no matter what might be the extent of the phlegmasia. It is true, I associated, in this therapeutics, faradization with galvano-chemical caustique. Faradization, in the form of a current of tension, calms the nervous system, diminishes excitability and relieves pain; but, of itself, is often insufficient to arrest the acute phlegmasia. The dynamic action in the commencement of inflammatory conditions is purely calmative, and will aid in the resolution of old exudates. I have associated three orders, of procedure, which, in inverse order of merit, are faradism, intra-uterine galvanism and vaginal

peripheric galvano-puncture. I will briefly sum up my views of each.

1. Faradization, under the form of a current of tension, made by the long thin wire, calms the nervous system, moderates its excitability, assuages or cures pain, but is often powerless to arrest an acute phlegmasia; its action is purely dynamic, and it acts, as opium acts, during early inflammatory stages, but is powerless to arrest the evolution of inflammatory processes. The current (faradic) of tension is the only one tolerable and indicated in acute and subacute forms. A current of quantity is less efficacious and less tolerable, except in rare cases of chronic exudates where, in acting upon the interstitial circulation, it aids reabsorption to a certain extent. The electrode should generally be the bipolar, to better localize the electric action, either in the vagina or in the uterus. All other things being equal, the uterine application is by far the most useful. The application should be in moderate doses without shock, and more gentle as the inflammation is more active. The séances should be daily at first, lasting from five to twenty minutes, and the dose progressively augmented as the patient can bear it.

2. Galvanization, or rather intra-uterine chemical caustique, is much more powerful than faradization, and will often be sufficient of itself in cases of ovaro-salpingitis. It is a most excellent way of changing in part or in whole the entire lining membrane of the uterus, and of setting up peripheric changes by derivation. The faradic current excites the nervous and muscular systems after the manner of a mechanical force, by interruptions and shocks. The galvanic current, however, is a physical and chemical force, at once caloric and trophic, and brings each of its factors into action separately or together as desired. All binary compounds and those of greater complication will tend to decomposition, and this decomposition, called electrolysis, will be in proportion to the electric energy given out, and to the length of time of the application. This interstitial breaking up of the elements, which will be preceded by a different orientation in the polarization of the organic molecules, tends, on the one hand, to bring around the positive pole the acids and oxygen, while the bases and hydrogen go to the negative pole. This serious molecular action ought to be sufficient for an intelligent theory of the effects of the galvanic current, but recent experiments which we have made place these facts upon an indisputable basis. My friend Laguerrière and myself have found that the galvanic current sent through culture media of pathogenic microbes is *germicidal*, thus confirming what I said long ago, that this current was *antiseptic*, and would *attenuate* or *sterilize* certain conditions of germ change. Applied in a given region the galvanic current acts locally and generally; each

pole has its undivided caustic action—the one acid, the other basic. The current is felt in the interpolar zone, engendering trophic changes, and tending to the resolution of certain pathological conditions.

The doctor of to-day who has not kept apace with the advance of gynecological science, lauds to his utmost the curette, which first saw the light in France, but has long since fallen into desuetude in the land that originated it. Without wishing to discredit a surgical procedure of value in certain conditions, the superior advantages of the intra-uterine galvanic current are beyond dispute.

(a.) It is simple and easy of application, requiring no assistant, and may be used by any one, no matter how little experience he has in gynecology.

(b.) Being but slightly painful, chloroform is not needed, this being only demanded in certain cases of puncture.

(c.) It is valuable among working women, as a short period of repose alone is necessary after the application, instead of hours and perhaps days in bed.

(d.) It can be gradually and gently applied by progressively increasing the strength, and is less brutal than the curette.

(e.) It is not contraindicated in any acute case of inflammation—the sole caution being to use extra care, and to increase the strength only as the patient is able to bear it.

(f.) It is an agent which, instead of being blind, obeys in a precise and mathematical manner the hand applying it; that is to say, one can measure and administer it and at the same time have an exact record of the amount of cauterization produced, to which three things conduce: the general intensity made use of, the density of the active electrode, and the duration of the application.

(g.) It is an active force, which will produce an active result localizable at will, and which may be concentrated upon any part of the uterine lining membrane desired.

(h.) It is absolutely harmless if proper antiseptic or aseptic precautions are made use of.

(i.) According to the intensity and duration its action can be varied, and also according to the active pole made use of; it may be made acid by using the positive pole, and basic by using the negative pole.

(j.) Apart from the curetting action of the chemical galvanism, which one can easily see, there is a more profound action trophic and vital, and which is propagated along the whole organic circuit between the two poles. Thanks to this last consideration, above all in the treatment of salpingo-ovaritis, this chemical galvanism has a power far above surgical curetting, chiefly in reaching the uterine parenchyma and adnexa.

(k.) If surgical *râclage* often results in frequent

returns of the disease, causing anatomical and functional troubles which it hoped to combat, I can affirm that these results are much less frequent by the electrolytic treatment, which may require several sances to produce a lasting effect, but which good results, as I have had reason to observe in my clinic, last for many years after the cessation of all treatment.

The operative technique is already sufficiently well explained in my various brochures upon the electric treatment of fibroma and endometritis. I shall content myself with giving you merely the salient features of the treatment of ovaro-salpingitis. The positive pole always causes less congestion than the negative, but the latter is more valuable to promote resolution. The positive pole should be used generally in the commencement, and once having passed the first stage of toleration, the negative pole should be substituted. The dominant preoccupation which should make us cautious in treating salpingo-ovaritis, and which is sometimes difficult of recognition, is the fear of finding ourselves in the presence of a pyosalpinx, which a large dose of galvanism would aggravate; so, when in doubt, begin very gently with a mild current to test the susceptibility of the uterus and peri-uterine tissues, then increase with the patient's tolerance and according to clinical indications. One may begin with 20 to 40 milliamperes. If the intolerance is great, respect it and do not increase; if well tolerated increase to 100–150 milliamperes. Here clinical diagnosis must be called in to differentiate between hysterical intolerance, that need not be heeded, and an inflammatory intolerance which must be respected. The sittings should not be too frequent. In the initial treatments they are frequently followed with a reaction more or less intense, which may last several days; generally we should wait until calm is reestablished. Sometimes the sances may be given once or twice a week, sometimes only every fifteen days. The same reasons must guide the doctor as to the length of a sance; sometimes they should last three minutes and sometimes five to eight minutes.

3. I now come to the third division, the most efficacious of all, the penetration with the galvanic current of one of the vaginal cul-de-sacs at the nearest point of the inflamed region. I mean *vaginal galvano-puncture*. There are two clinical indications, the one of *choice*, the other of *necessity*. The indication of choice presents itself when one finds himself in presence of a salpingo-ovaritis which has not been sufficiently ameliorated by the intra-uterine galvanism. It is necessary then to penetrate the mass in the point the nearest possible to the diseased spot, in order to lose nothing of electric force, which now should seriously concern itself with the suffering point. Theoretically the application, well made, should be most efficacious, and no doubt rests in my mind that such is

the case, for the reply of all the patients who have submitted to this plan is that the punctures were much more painful but much more efficacious, because often one puncture gives more relief than many simple intra-uterine applications. The indication of *necessity* for galvano-puncture is when a fluctuating tumor impinges upon the vagina, and which should be drained antiseptically through the vagina.

Already many years ago I gave the rules for the essentials of galvano-puncture. I will only now cite the chief points:

(a.) Here, as in all electrical treatment, be it faradic or galvanic, one should precede everything with thorough antiseptics, preceding and following every operation with an antiseptic vaginal irrigation, either of sublimate, carbolic acid, creoline or naphthol. Between the séances we will do well to close the vaginal cavity with iodoform gauze (or sublimate or salol gauze), to insure perfect asepsis, as well as to prevent sexual congress, which should be suspended.

(b.) With the preceding electrical treatment it is not necessary to remain in bed. I exact from my patients only one or two hours of repose after galvano-caustique, without denying, however, that a longer period might be beneficial. Galvano-puncture, however, requires at least two or three days of rest in bed after each puncture.

(c.) The trocar carrying the current should be the smallest possible, but of sufficient resistance not to be easily broken. Steel is the best, because it penetrates easily.

(d.) The chief point is the depth of the puncture. A slight puncture of a *half centimetre*, as an average, suffices to make a door of entrance for the current in the region which it is to traverse. Deeper punctures do not suffice any better to attain such an end; on the contrary, as I have seen, they may be dangerous. I proscribe all punctures over 1 centimetre.

(e.) Where make the puncture? Questions of choice and necessity here come up. The choice is to puncture as near as possible the diseased portion, but necessity forces us to avoid at all cost the anterior cul-de-sac on account of the bladder. The lateral, and above all the posterior regions are the most favorable for the puncture. I make them oftenest in the posterior cul-de-sac, in the middle of the pouch of Douglas, directing the axis of the instrument toward the uterus in order to avoid the rectum.

(f.) This operation, much more painful than galvano-caustique, is often tolerated by certain women, but in others chloroform will be required.

(g.) I *never use a speculum* in this operation, which can only be well and delicately carried out as follows: One fixes at first the exact length of the puncture, by turning the screw and advancing the steel point to the required length beyond the celluloid, then, having fixed with the index finger

the exact point to be punctured, and having made sure that there is no arterial pulsation, one slides the celluloid up to the point, which serves as the conductor for the trocar, which is then plunged in.

(h.) The number of punctures demanded is variable. Some cases of hydro- and catarrhal salpingitis yield to one puncture, some require three or four, and tubercular tubes even more.

Generally these cases require much longer periods of intermediate repose than cases of galvano-caustique, because at their commencement they are often followed by a severe reaction, which may last many days. The application should not be renewed until all of the symptoms have disappeared.

(i.) As to intensity and choice of poles I repeat what I said just now when speaking of intra-uterine galvanization. The intensity will vary from 20 to 50 milliamperes. To go beyond this is to go beyond the point of tolerance, and chloroform should be used. To create a temporary vaginal fistula 100 to 250 milliamperes will be required.

(j.) The puncture should generally be positive at first, because it is more tolerable and less exciting than the negative. This latter is employed when a more powerful action is demanded. Especially in presence of a fluctuating tumor pointing into the vagina, in which a fistulous tract is to be made and vaginal drainage established, is the negative pole demanded.

(k.) Should febrile excitement arise, all treatment is to be suspended. One may think himself in the presence of a pyosalpinx, if it points into the vagina, and a puncture is not contraindicated; but if it is high up, not accessible, and far from the vaginal cul-de-sac, a deep puncture, which might cause an evacuation into the cavity of the peritoneum of the sac, is to be avoided. It is here that surgery must step in to carry out its legitimate functions.

My clinical experience, which is now seven years old, has given me many cases of salpingo-ovaritis, which I hope later on to tabulate. I shall content myself now with some results of my treatment. Every salpingo-ovaritis will generally be suitable for appropriate electrical treatment, and this should be the conservative method of choice; it is sovereign in catarrhal salpingitis, only calmative in tubercular salpingo-ovaritis, and in certain pus tubes may be of great service. Whatever electric treatment is made use of, it should be continued until the patient pronounces herself cured of her symptoms, and until an examination has satisfied us that the anatomical change is considerable. Surgical interference should never be resorted to until after all electrical resources have been exhausted. Castration, which morally and physically mutilates a woman after an incurable fashion, and only cures radically in a fourth

or fifth part of the cases, should be only an operation of necessity, never of choice, and should be regarded as a last resort. Electrical conservative therapeutics, harmless, easily applied by any one, and which does not pretend to cure every case of salpingo-ovaritis, finds its greatest triumph in rendering a *subsequent conception* possible, as I have seen in several of my patients. I will not harass you with the details of all of the cases that have been to me for treatment, but will content myself with giving you full details of two typical cases, in one of which there were two subsequent conceptions, the other remarkable clinically, and though long it is full of interest, demonstrating that electricity, persisted in and rightly used, may be of the greatest value in the different troubles that may beset the same patient.

#### COMPLETE HISTORY.

Madame Sophie Edinger, æt. 34 years, living at 5 Rue de l'aqueduc, Paris, presented herself at the clinic of Dr. Apostoli, August 17, 1886.

*Previous History.*—Nullipara, neither pregnancy nor miscarriage. Born in Lorraine. Has lived at Paris for seventeen and a half years. Mother died at the age of 48 in consequence of a profuse uterine hæmorrhage, the cause of which was unknown. Menstruation easily established at the age of 11. Since its appearance it has been of the following regular type: Occurring at fixed intervals, the flow has lasted on an average six days, and has been *painless*; it has always been *very* abundant, and often accompanied by the expulsion of clots. At 13 and at 17 years of age, without an appreciable cause, the periods were suppressed for about two or three months, without other morbid phenomena. Slight, intermittent leucorrhœa.

Of a rather delicate and lymphatic temperament, the patient had several of the diseases of childhood, eczema of the head, and frequent attacks of gastritis which often caused vomiting of the food. At 28, a light attack of rheumatism, localized in the two arms, which lasted one week.

Married at 29 years of age. From the beginning of her marriage her health has been disordered. The most striking phenomena from the first were the menstrual troubles characterized by an increase in the quantity of the flow, by its more frequent occurrence, and by pain preceding the flow for one or two days and disappearing as soon as it was established. Her married life, then, was marked for five years by the appearance of a *true dysmenorrhœa*, very intense, which has persisted until to-day, and which often obliged her to go to bed. Usually the pain disappeared suddenly on the appearance of the flow.

Since her marriage her general health has also been disordered; she began to grow thin, and her appetite became capricious. This condition persisted for three years, during which time she

worked, though with difficulty. For two years past (1884–1886) her condition has become progressively much worse. The pain, formerly intermittent and premenstrual, has become almost constant, interfering with the walk, making standing impossible, and localizing itself as a continuous dragging or tension in the right iliac region, radiating posteriorly to the lumbar region, and anteriorly to the right groin, involving further the entire corresponding thigh as far as the knee. This pain has increased greatly, without changing the condition topographically, at the time of the periods most of all, obliging the patient to take a forced rest.

For some months after the marriage the sexual relations were very painful. Then the pain disappeared, to reappear again two years ago with much greater intensity, finally making all sexual relations impossible. Intercourse also provoked and increased the pain in the right iliac region. The patient has never, up to this time (1886), had any pain in the *left* iliac region. *For eight months the patient scarcely left her bed*, attacked by pain so intense as to cause her to cry out involuntarily; this was accompanied by almost daily vomiting of sometimes alimentary, sometimes bilious matter. She grew thin more rapidly and her appetite became more and more perverted, while the digestion became more painful. The abdomen was extremely sensitive, and the pain was always localized on the right.

She was also decidedly constipated. The menstruation was at times transformed into a veritable metrorrhagia, an almost constant flow with an interval of only one week between the periods.

The patient was treated regularly by Dr. Mandet, who applied the usual classic treatment of emollients, milk *régime*, opiates, revulsives upon the abdomen, etc. It was at the instance of her physician that she came to consult us, on account of the total lack of success of the most varied and assiduous treatment that had been instituted.

*Actual Condition August 17, 1886.*—The patient is humble, impressionable, nervous, but not hysterical, so feeble, and suffering to such a degree, that she had to be brought to the clinic in a carriage and assisted upstairs. She is emaciated, without color, and exhibits a state of considerable suffering. On palpation the abdomen is painful, and sensitive in the two iliac fossæ, especially in the right. For a year it has been impossible for her to remain erect without an abdominal support.

The internal examination is difficult on account of an excessive sensibility of the uterus, and especially of the cul-de-sac. An inflammatory exudate entirely surrounding the uterus constitutes a single mass, adherent to the sacrum, to each side of the pelvis, and enclosing the uterus.

An examination shows at times in the middle of this total cellulitis, which envelops the uterus, a plane, subadjacent, more resistant and fibrous,

which indicates the presence of an interstitial uterine fibroid, localized especially at the right and anteriorly.

*Diagnosis.*—Peri-uterine and subacute inflammation with interstitial, subadjacent fibroid, and ovarian salpingitis. Pronounced retroversion. Sound measures 7 centimetres.

*Treatment.*—August 21, 1886. *First, intra-uterine negative galvano-caustic, 100 milliampères, for five minutes.* Two hours after the treatment the patient returned home.

September 9, 1886.—Patient reports that she has had a flow lasting twelve days, which began the day after the first treatment, and which has greatly fatigued her. This flow is probably due to the first operation (treatment), which was wrong. This was *negative* and ought to have been *positive*. This flow was accompanied by an increase in the vomiting already existing. In order to calm the patient, she was given an *intra-uterine, bi-polar faradization of tension, with the fine wire, for five minutes*, and starting with to-day, in order, hereafter, to carry on this treatment simultaneously with the treatment of the uterus, *the bi-polar galvanization of the pneumo-gastrics was begun*, to alleviate the gastric phenomena, the most serious of which is the vomiting.

This galvanization is given at a dose of 5 to 12 milliampères, for five to fifteen minutes each time.

September 21.—*First positive, intra-uterine galvano-caustic* (made with the object of arresting the hæmorrhage), 175 milliampères, five minutes.

Sept. 30.—*Second positive galvano-caustic.*

Sept. 30.—*Third positive galvano-caustic—idem—150°, five minutes.*

The last period occurred Sept. 22, and lasted six days. The vomiting of food, which was incessant, and almost daily before the beginning of the treatment, has been overcome at the onset by the galvanization of the pneumo-gastrics, which has not only put her in a condition to tolerate the milk which she had been ordered to take, at the clinic, but also has again given her an appetite, almost unknown before.

October 7.—*Re-commencement of the negative galvano-caustic in order to accelerate the absorption of the exudate.* Second negative galvano-caustic, 80°, five minutes.

October 12.—*Third negative galvano-caustic, 80°, three minutes.*

It was necessary to discontinue the treatment after a sitting of three minutes, on account of the *mal au cœur* of which the patient complained. Strength is restored, the stomach performs its functions much better. Since the beginning of the treatment she has never vomited on the days of treatment, and in the intervals has vomited but rarely. For fourteen days there has been entire absence of vomiting. She begins to walk more easily, and with less pain, but still suffers when sitting. The constipation persists. She has con-

stant numbness in the right leg. She is still obliged to keep her bed almost all the time, and only leaves it to come to the clinic.

October 14.—*Fourth negative galvano-caustic, 100°, five minutes.*

October 19.—*Fifth negative galvano-caustic, 100°, five minutes.*

Has had her menstrual period since this morning, but with much less pain. The complexion is clearer and the expression better.

October 21.—Menstruation continues; flow abundant, but there is no menorrhagia.

October 26.—Vomiting again on the 23d and 24th. *Fifth negative galvano-caustic, 100°, five minutes.*

November 4.—*Sixth negative galvano-caustic, 150°, five minutes, badly borne.*

November 6.—*Seventh negative-galvano caustic, 60°, five minutes.*

November 9.—*Eighth negative-galvano caustic, 60°, five minutes.*

The vomiting has quite ceased; only a slight nausea remains. The appetite and digestion are always better on the days of treatment: the day following she is sometimes not quite as well. There is an equal improvement on the part of the abdomen; it is less sensitive on pressure, and swells only when she is tired from walking. For fifteen days she has been able to sit up part of the day.

November 11.—Patient is menstruating and (a fact most characteristic in favor of her improvement) she has suffered much less than usual, and has not had to go to bed. She has been able to walk alone without support, a thing which formerly was impossible in this condition. She declares herself completely transformed.

November 11. *Eighth galvano-negative, 90°, five minutes.* An internal examination shows an appreciable change. The half of the exudate has disappeared, and on the right it has left bare the sub-adjacent fibroid, the diagnosis of which is emphasized to-day. The uterus begins to be movable, and can be slightly displaced.

November 20.—*Ninth galvano-negative, 100°, five minutes.*

November 27.—*Tenth galvano-negative, 80°, five minutes.* Since the beginning, each treatment is followed by an antiseptic vaginal injection, after the method of Van Swieten, and a tampon of iodoform gauze is left in the vagina.

November 30.—Patient has just had a return of her former painful symptoms, without an appreciable cause. This lasted eight days, and was marked by a reappearance of the old vomiting. Galvanization of the pneumo-gastrics, which produced immediate relief. The weight is increasing; without the clothing it is 118 pounds.

December 2.—Amelioration of the abdominal pain. No vomiting since November 30. *Eleventh galvano-negative, 80°, five minutes.*

December 4.—Twelfth galvano-negative, 60°, five minutes. The patient is becoming more intolerant of the action of the galvano-caustics, but each time she feels greatly relieved by it, and sleeps better the night following.

December 23.—Thirteenth galvano-negative, 80°, five minutes. Patient feels well. The gastric troubles have disappeared; she walks better, but is still unable to do her housework.

December 28.—On account of the intolerance which begins to be manifested for the galvano-caustic which, at the beginning, was well borne at 100°, and now is somewhat painful at 60° or 80°, and in order to hasten the cure—which may be considered as still in the rough—both anatomically and symptomatically, the galvano-punctures are begun.

First vaginal negative galvano-puncture at a depth of one centimetre in the right-lateral cul-de-sac, with a filiform trocar of steel, at 200° milliampères, five minutes. Patient under the influence of chloroform. Vaginal injection of sublimate solution 1-1200 before and after the séance, vaginal tampon of iodoform gauze. Patient remained at the clinic for six days without leaving her bed. Vomiting appeared the evening of the day she was treated and the following day, and was relieved by the galvanization of the pneumo-gastrics.

Menstruation occurred December 31, ten or twelve days in advance, of average quantity, though rather less than formerly. For the first time since her marriage the menses appeared *without pain* and without the formation of clots. A complete calm has followed the appearance of the menses. The patient has eaten with a good appetite and has recovered her power to sleep, which she had lost for a long time. In a word, she feels as if she were transformed, and she seems to have derived more benefit from this first puncture than from all the preceding galvano-caustics.

January 4, 1887.—The patient left the clinic to return home. Since then her health has constantly improved. The following is a statement of the typical modifications which have been progressively determined from the 4th to the 22d of January, 1887:

1. Walking has become much easier. The patient is able to come to the clinic without the companion hitherto necessary. She is much less fatigued than formerly by the jolting of the carriage.

2. She is able now, for the first time, to do her housework, discontinued eighteen months ago.

3. Digestive functions good. She has more appetite, while the nausea and vomiting have ceased.

4. Parallel transformation, anatomically speaking. On examination the peri-uterine sensibility is less acute. The retrogression of the exudate makes rapid progress.

5. Restoration of all the functions, and notably considerable diminution of the abdominal pain.

Every two days she has had an antiseptic vaginal injection, and the tampon of iodoform gauze has been changed.

January 22.—Second negative, vaginal galvano-puncture, to the right, at a depth of 1½ centimetres; made this time without chloroform. The pain limits the intensity to 50 milliampères, eight minutes. The patient did not remain at the clinic but returned home the same evening. Slept well and did not suffer. The menses appeared the next day, five days in advance, and for the second time without pain and less profuse.

January 25.—Antiseptic vaginal injection.

January 29.—Walking is still easier, patient finds herself "very light."

February 10.—The orifice made by the last puncture is closed. Third negative, vaginal galvano-puncture, at a depth of one centimetre, 60°, five minutes, without chloroform. Antiseptic injection, and vaginal tampon of iodoform gauze.

February 12.—Patient suffered for some hours after the last puncture, although she was able to go home that evening. She was rather more tired than after the previous punctures, and attributed this to the fact that the operation was done without chloroform.

February 15.—For the first time in eighteen months the patient has had sexual intercourse, which was effected without too much pain.

March 5.—Galvano-puncture without chloroform was attempted. Patient was unable to tolerate it, and after some seconds the application was discontinued. Nausea and efforts to vomit rendered the continuation impossible and unbearable.

March 8.—The evening following this aborted puncture there was a recurrence of the abdominal pain. The next day, March 6, menstruation began, for the first time in her life eight days late. Unlike the three last periods, the flow has been more abundant, painful, and accompanied by the expulsion of clots. The question arises, in view of the recent sexual relation and of the delay in the menstrual function, so abnormal, if this, as seems probable, was not a miscarriage? There was also a renewal of the digestive disturbance, but without vomiting.

March 19.—Fourth negative galvano-puncture, in the posterior cul-de-sac, under chloroform, 150°, five minutes.

March 22.—Patient remained in bed at the clinic 24 hours. She suffered a little after this puncture, but found herself again very much improved. From this date the patient, who has had three times a week antiseptic vaginal injections, and tampons of iodoform gauze, finds herself again progressively improved. One month after, the orifice made by the puncture had not closed. The uterus begins to be easily movable.

April 20.—For the first time in years the pain seated in the plane of the right iliac bone, and radiating posteriorly and anteriorly, has disappeared. Continued anatomical improvement.

May 3.—On examination the fibroid appears to-day very clearly marked, and the inflammatory exudate can only be perceived on deep pressure. The mobility of the uterus increases. Fifth galvano-puncture (negative) in the right lateral cul-de-sac, at a depth of one centimetre, 150°, five minutes, under chloroform.

May 5.—Patient vomited the evening of the treatment and the day following, due probably to the great amount of chloroform absorbed. She remained 24 hours at the clinic. Since the puncture the amelioration has been on the increase. Patient has continued to come to the clinic three times a week for the galvanization of the pneumo-gastrics, and to have the iodoform tampons changed.

June 4.—The following is a statement of the actual condition:

1. Patient has just taken a long walk without fatigue.

2. All spontaneous pain in the right groin has disappeared.

3. Menstruation in April and in May occurred, after a delay of two to four days, *without pain, and less profuse*, lasting five to six days. Slight *malaise* at the end of the periods.

4. The complexion is better, she has more color, and has lost the former deathly hue.

5. She feels transformed, strength recovered, and says she is able to work.

6. The constipation has disappeared. Patient has a daily movement of the bowels.

7. The patient, comparing the benefit from the galvano-caustics with that from the punctures, affirms that the benefit from the latter is very much greater, especially from the punctures made under chloroform, at a higher dose, which proves that the effect increases with the intensity, other things being equal.

8. Patient has never been as well as at present since her marriage.

9. The sexual relation is not very painful.

10. From an anatomical point of view the exudate has been reduced three-fifths. The patient remains under observation, and it is probable that no new interference will be necessary, since she believes herself nearly well from every point of view, and capable of leading the active life of a tradeswoman.

June 7.—Patient weighs 119 pounds. (In December she weighed 118 pounds.) Dr. Apostoli made a futile attempt to pass the sound. This was painful and could not be completed. In the evening the patient had a bloody discharge, which was certainly provoked by the attempt to pass the sound. This discharge continued almost without interruption from the 8th to the 16th of

June: it was neither accompanied nor preceded by abdominal pain.

June 18.—The discharge has been arrested since the 16th, since which time there has been an offensive return of the pain in the right iliac fossa.

June 21.—The old gastric disturbance reappeared the day before yesterday: the patient vomited, and was obliged to come to the clinic for the galvanization of the pneumo-gastrics. Walking is again difficult, and the countenance is once more depressed in consequence of the relapse, which can only be attributed to the sound. With the single object of calming the patient, a first vaginal faradization was immediately given, using the large bi-polar vaginal sound, the extremity of which was applied against the right lateral cul-de-sac, the most painful part. Application of a *current of tension, with the fine wire, with slight intensity, for fifteen minutes.*

The acute pain disappeared immediately after the treatment, the expression became better, and walking easier. Patient continued to be relieved during the evening and somewhat the next day: on the third day there was an offensive return of the old symptoms.

June 23.—Third vaginal faradization, identical with the first, lasting ten minutes, with the same amount of relief.

June 24.—Third faradization, ten minutes.

June 25.—Fourth faradization, ten minutes. Since the 22d the amelioration of the pain has been progressive, and parallel with this the gastric trouble, which always occurs with the pain, has been relieved. The patient has not vomited, indeed, since the 22d; the digestive functions are re-established, walking is easy, and sleep good.

June 30.—In order to bring about the complete resolution of the remainder of the old exudate, a sixth negative, vaginal galvano-puncture was made to-day, *to the right posteriorly*, in the most prominent portion of the fibroid, 180°, five minutes. Depth of puncture, one centimetre. Patient chloroformed. Remained at the clinic 24 hours without any incident worthy of note, and returned to her home the next day.

July 2.—No loss of blood. Patient suffered very little after the puncture. She had a little nausea, but did not vomit. Antiseptic vaginal injections, and tampons continued.

July 12. Menstruation continued from the 4th to the 7th, moderate in quantity, without clots, and without pain either before or during the flow. Since the cessation of the menses the patient has suffered for three days, and has had a return of the gastric trouble. The abdominal pain is better to-day. *Intra-uterine faradization*, with the fine wire, for *five minutes*, badly borne. Galvanization of the pneumo-gastrics continued.

From July 19 to August 20 the patient continued her visits to the clinic regularly three times

a week. *Bi-polar vaginal faradizations with the fine wire* have sufficed for treatment. Thus she has had *seven successive sittings of five to eight minutes each*, the result of all of which has been to increase progressively her *bien-être*, and to relieve all abdominal pain. One month after the last puncture the orifice made by it had not closed, but the patient was able to continue her occupation, in spite of the presence of a temporary vaginal fistula, thanks to the antiseptic precautions which have been carefully observed. Conjointly with the vaginal treatment the galvanization of the pneumo-gastrics has been carried on, according to the indications and, as usual, each séance has been followed by an immediate alleviation of all the gastric disturbances.

October 16, 1887.—Patient has been so well that she suspended her visits to the clinic after the 28th of August. She walks easily, does not suffer, and has no pain during sexual intercourse. Her sleep is good, she eats well, and digests easily. The abdomen is no longer painful, even when she is tired. She is scarcely sensible of a slight dragging the first day of her menstrual periods. Total absence of leucorrhœa.

January 12, 1888.—Excellent health since the last visit. Patient has worked constantly and been able to do really hard work since October, and this without interruption during her periods, which last on an average six days. On palpation, one finds absolute insensibility of the abdomen. On internal examination, the uterus is found to be movable, the peri-uterine exudate is almost entirely absorbed, and there is marked diminution of all sensibility, even with deep pressure.

January 26, 1888.—Same good condition. The journeys which she is constantly obliged to take, even during menstruation, do not fatigue her.

April 16, 1889.—Of her own accord the patient has discontinued all visits to the clinic since January, 1888. She comes to-day by special request. Her health has remained perfect in every particular, and she believes herself radically cured, because all the functions are normal. She has not been indisposed for a single day, and has continued her fatiguing work without interruption.

*Actual Condition, April 16, 1889.*—Complexion fresh and of good color, giving every evidence of health. Walking very easy. Erect position not at all painful. Menstruation is always regular. It occurs on a fixed day, without delay. The quantity diminishes progressively. Formerly the flow continued six days, at present it lasts but three or four days. There are no clots. *There is complete absence of pre-menstrual dysmenorrhœa.* She feels only a little tired, and slight abdominal pain before the appearance of the flow. She is always able, even during her menstruation, to work easily and without fatigue. Vesical functions normal; no constipation; complete absence

of leucorrhœa; sexual relations are rather painful. *Palpation*: the two iliac fossæ are not at all painful.

*Internal Examination.*—Neck in normal position. Uterus movable, without appreciable sensibility. Absence of pain on touching the cul-de-sac, but a deep exploration causes rather acute pain in Douglas' pouch, very little laterally. The uterus is easily displaced laterally, but on raising it is found to be slightly adherent to the sacrum.

With a deep touch the right ovary can be felt, also the right Fallopian tube, which no longer seems to be inflamed. The rectal examination confirms what has been determined by vaginal examination. All efforts to pass the sound—even a very small sound—are futile. The sound is arrested by an almost complete atresia of the external orifice.

*Nota Bene.*—This absence of dysmenorrhœa, which is coincident with a considerable degree of uterine atresia, is a new fact, which, with the addition of those which I already possess (in all a very large number) stands in favor of the thesis which I have sustained for a long time, the frequent independence of dysmenorrhœa, and uterine atresia, and confirms this proposition: *Dysmenorrhœa is almost always of ovarian origin, very rarely of uterine origin.* The patient affirms again to-day that, judging without appeal, the respective results of the different treatments that she has undergone, she has derived the greatest benefit from the galvano-punctures, although more painful and often scarcely to be endured without chloroform.

In order to get all possible information on the origin of the disease, I saw the husband to-day (April 23, 1889), for the first time, who stated that he had, in 1878, while in the army, a manifest gonorrhœa, characterized by pain on urination, and a discharge *sui generis*. He claimed to have been rapidly cured of this disease by the usual treatment. Five years after this he married, and it is possible that in spite of his statement he had still, at this date, an unknown gonorrhœa, which must have been the point of departure, as is usual, of the peri-uterine accidents of his wife.

#### SECOND OBSERVATION; SUMMARY.

Madame Marie Elien, domestic, aged 22 years, presents herself at the clinic of Dr. Apostoli June 9, 1885; nullipara.

*Antecedents.*—No hereditary antecedents, habitual good health, no diseases of infancy, menstruated at 17 years of age, scantily during two days on an average, and without pain. Married at 21 years, pregnant immediately after, prematurely confined in seven months, after a fall on March 13, 1885. Immediate consequences apparently good, and probable commencement of the

present malady six weeks later at the time of the menstrual return. Profuse metrorrhagia, which has existed a month, and acute pains in left side of abdomen, work impossible, sexual relations very painful. Has kept the bed for a month with fever. Gastric troubles.

*Diagnosis.*—Endometritis. Double prolapsus of the uterine annexes, and left ovaro-salpingitis. Uterus bound down.

*Treatment.*—First galvano-cauterization, intra-uterine, negative, 100 milliamperes, five minutes.

June 13.—Improvement as to the pain. Metrorrhagia continues.

June 16.—First galvano-puncture, vaginal, negative, made in the posterior cul-de-sac, with a fine steel trocar, to the depth of one centimetre, without anæsthesia, 80 milliamperes, five minutes. Rather lively reaction the same evening of the operation, which became calmed in the night, and after which she was better. Continuation of the metrorrhagia.

June 18.—Disappearance of the pains—has not kept the bed since the beginning of the treatment.

June 23.—Expulsion of a slough last evening and considerable diminution of the retro-uterine exudate, as well as of the vaginal sensibility.

June 30.—The same good condition.

July 4.—Marked improvement.

July 9.—All flow has ceased.

July 11.—Second galvano-puncture, vaginal, negative, in the posterior cul-de-sac, to the depth of one centimetre, 100 milliamperes, five minutes, without anæsthesia, and without a sojourn at the clinic—only rested two hours, the same as at the first time.

August 4.—No inflammatory reaction as a result of her last puncture. She has been able to endure easily a journey into the country, from which she has just returned after an absence of three weeks.

August 8.—Same good condition. Third galvano-puncture, vaginal; negative, 50 milliamperes, five minutes.

Sept. 12.—Improvement persists. Walking is more easy.

Sept. 17.—Fourth galvano-puncture, vaginal, negative, 50 milliamperes, five minutes.

Sept. 22.—Fifth galvano-puncture, vaginal, negative, 50°, five minutes.

Sept. 29.—Offensive return of the pains under the influence of a great fatigue and the renewal of the sexual relations in spite of our injunctions to the contrary. Fresh metrorrhagia.

Oct. 6.—All is quieted, the flow is arrested, and she does not suffer.

Oct. 13.—The improvement continues, the posterior puffiness has almost disappeared, and she can be considered as cured.

Oct. 22.—Another galvano-puncture made

solely for the purpose of perfecting the cure. Sixth and last galvano-puncture, vaginal, negative, made as the preceding ones, to a depth of one centimetre, without anæsthesia, and with the aid of a small steel trocar, after having taken all the precautions possible for vaginal antisepsis before and after each treatment. No sojourn at the clinic, repose only for two hours. All of these galvano-punctures, although painful, were in general well tolerated, and were not followed by any inflammatory reaction.

Oct. 30.—She is very well, she is cured symptomatically and anatomically, all the exudate has disappeared; but the uterine annexes remain prolapsed, a deep and quite forcible vaginal pressure is necessary in order to provoke sensibility. She ceases all treatment spontaneously.

Jan., 1886.—Beginning of a *second pregnancy*, during which she can continue her work without interruption.

August 30.—Premature confinement at about seven months without appreciable cause, expulsion of a dead fœtus, immediate results good, almost immediate resumption of her work.

Oct. 6.—Same good condition as a year ago. The uterus can be displaced laterally, but preserves still some posterior adhesions. Defecation, previously painful, is easy and causes no longer sensitiveness. To resume, a year after cessation of treatment the patient remains cured. Symptomatically and anatomically she remains very much improved, her health is perfect in every direction and the sexual relations, impossible before the treatment, provoke no longer any sensitiveness.

January, 1887.—Commencement of a *third confinement*, which developed normally.

Oct. 21.—Normal confinement at term, and results of the lying-in good. Resumption of her domestic work almost at once. Nurses her child.

May 12, 1888.—She has not kept the bed a single day, and has not lost the benefit of her treatment, same anatomical condition, same prolapsus of the uterine annexes, especially the left, without any inflammation.

August.—Commencement of a *fourth normal confinement*, during which she worked constantly.

April 28, 1889.—Confinement at term. Sequelæ of the lying-in excellent, no pains in the abdomen, no leucorrhœa, was able to recommence her work on the tenth day.

June 8.—Is very well, all her functions are normal, she nurses her child.

*Local Examination.*—On pressure, a slight ovarian pain in the left iliac region is observed, the uterus is normal, very movable laterally, but cannot be lifted without a little difficulty, on account of the posterior adhesive bands, same prolapsus of the annexes, more pronounced on the left, with one tube in the recto-vaginal wall, no signs of salpingo-ovaritis.

To resume, the treatment, composed of *one galvano-cauterization and of six galvano-punctures*, had an immediately favorable result, symptomatically and anatomically, which survived four years after, and which permitted the evolution of *three consecutive confinements, of which two were at term*.

#### OBSERVATIONS ON OVARIAN SALPINGITIS; SUMMARY.

Woman, aged 34, multipara, scrofulous. Until the age of 29 menstruation regular, abundant, and without dysmenorrhœa. Married at 29. Sudden appearance immediately after of an intense, premenstrual dysmenorrhœa. Sanguinous flow and frequency of periods increased. Same unfortunate condition for three years, making work often difficult. For two years progressive aggravation of the local condition: continual abdominal pain, walking almost impossible, daily vomiting, suspension of sexual relations because so painful, beginning of an almost continuous metrorrhagia, unsuccess of all classic treatment. After remaining in bed for eight consecutive months almost all the time, the patient presented herself at clinic August 17, 1886.

*Complete peri-uterine inflammatory exudate, with subadjacent fibroids, and right ovarian salpingitis.*

From August 21 to November 23, 1886, thirteen negative, chemical, intra-uterine galvano-caustics of 60 to 150 milliampères, five minutes each, with two galvano-positives at the beginning, to arrest the existing metrorrhagia, and, in addition, bi-polar galvanization of the pneumogastries three times a week.

Marked anatomical retrogression and considerable symptomatic amelioration. In order to perfect the cure, from December 28, 1886, to June 30, 1887, six negative, vaginal galvano-punctures at a depth of one centimetre, posterior and to the right; two, without chloroform, at an average of 60 milliampères, five minutes each, and four, with anæsthesia, of 150 to 200 milliampères of five minutes each. Amelioration more marked and rapid under the influence of the galvano-punctures. Some vaginal and intra-uterine faradization of *tension*, with the fine wire, were practiced to alleviate the pain, and, simultaneously, galvanization of the pneumogastries, which were always victorious over the gastric troubles.

Suspension of all treatment in August, 1887. At this date the patient declared herself symptomatically cured. Walking easy, riding well borne, difficult work tolerated even during the periods, entire disappearance of all spontaneous pain, increase in strength, better health than for several years, menstruation regular, disappearance of all dysmenorrhœa. Anatomically the retro-uterine inflammatory exudate has almost disappeared.

From August, 1887, to March, 1889, all the functions have been normal and the cure has remained well defined.

#### THE ETIOLOGY OF LEPROSY.—A CRITICISM OF SOME CURRENT VIEWS.

*Read in the Section on Dermatology and Syphilography at the Fortieth Annual Meeting of the American Medical Association held at Newport, R. I., June, 1889.*

BY P. S. ABRAHAM, M.A., M.D., B.Sc., F.R.C.S.I.,  
OF LONDON, ENG.

LECTURER ON PHYSIOLOGY AND HISTOLOGY, WESTMINSTER HOSPITAL MEDICAL SCHOOL; CLINICAL ASSISTANT HOSPITAL FOR DISEASES OF THE SKIN, BLACKFRIARS; AND LATE CURATOR OF THE MUSEUM AND MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS IN IRELAND.

Putting to one side, for the present, the bacillus, which all pathologists agree is to be found in every leprous neoplasm, the supposed etiological factors of leprosy which have been most considered of late years, are three, viz., (1.) Heredity. (2.) A diet of fish. (3.) Contagion.

*The theory of heredity* has had immense support, both lay and professional, and it is curious to observe how loth some medical authors are to set themselves free from its trammels, or to question its influence in propagating the disease, even though many of the facts which they themselves adduce seem obviously to lead to quite another conclusion. As Mr. Jonathan Hutchinson points out,<sup>1</sup> the fact of leprosy occasionally appearing in healthy immigrants, and just as severely as if such persons belonged to leper families, is enough to prove that hereditaryness goes for little or nothing in its causation. It is indeed idle to deny the liability of leprosy to attack individuals who have not the slightest hereditary taint.

In a recent paper,<sup>2</sup> my friend, Dr. Blanc, who has in late years seen probably more cases of leprosy in the United States than any one observer, shows that in forty-two cases treated by him, twelve were natives of foreign countries (seven German, one Austrian, one English, one Irish, one French, one Italian), and of the remainder, eighteen were the children of foreign born parents (chiefly German and Irish), "from which we conclude," he says, "that if the disease is hereditary, it must be derived from a variety of foreign sources; and if acquired then it seems to attack the children of immigrants as often as those of the older native families." What evidence can be stronger against heredity?

An important paper on the Heredity of Leprosy has lately been published by Dr. G. A. Hansen,<sup>3</sup> who made a journey to North America last year to see what had become of the Norwegians who had gone there as lepers or had de-

<sup>1</sup>Clinical Lecture on "Leprosy, its Cause," etc.—Med. Press and Circular, Nov. 4, 1885.

veloped leprosy after their arrival in the new world, and to study this question of heredity in particular. With the help of Dr. Hogh, of Minneapolis, and Dr. Grunwald, of Minnesota, he was able to find out that about 160 Norwegian lepers had been established in the states of Wisconsin, Minnesota, and Dakota. Many of them are married, and several have left a good many descendants. There are, in addition, many other Norwegian immigrants who are either descended from lepers, or have leprosy relations in Norway. There is, therefore, in those districts, considerable material for the inheritance of leprosy. Of the 160 leper immigrants only thirteen are left, which he himself saw, and besides these there are perhaps three or four others. All the rest are dead. Of all their descendants whom he has seen as far as the great grandchildren, not one has become a leper. This is, in short, the result of his investigations; and he says there can be only one explanation, viz., that leprosy is not inherited.

*The Fish Theory.*—In reference to this old theory, Mr. Hillis wrote in 1881 that it "may now be laid aside as obsolete;" and it is, I believe, almost universally discredited by the medical men in Norway, as well as in every other part of the world where leprosy is rife. Nevertheless, one who is justly regarded as one of our highest British authorities is still, it seems, an ardent believer in the view that the disease is contracted by the eating of fish, more especially fish which has been somewhat decomposed, or has been salted.<sup>4</sup>

Those who oppose this theory may well point out that while numbers of people in Scandinavia, in Africa, and in other countries, habitually regale themselves with imperfectly cooked or decomposed fish, and do *not* get leprosy, numbers of those who *do* acquire the disease are not aware of ever having eaten anything of the kind. (This negative argument is apparently at least as good as that largely relied on by the anti-contagionists, who infer that because many persons who come in contact, or even live with lepers, do not become lepers, therefore the disease cannot be contagious under any circumstances.)

If, indeed, it must be through *one* particular article of diet, in all parts of the world, that the germ of leprosy is introduced into the system, why may we not select something which everyone must swallow at some time or other, such as, for instance, bad water? Filters and other precautionary measures are, at any rate, not particularly fashionable in leper countries.

We really have no direct arguments against a possible dietetic origin for leprosy, *i. e.*, at least by means of contaminated food; and the view of Dr. Living promulgated in his Gullstonian Lectures so long ago as 1873,<sup>5</sup> viz., that the disease may

be "propagated by the inhibition of the excretions of those affected, much in the same way as typhoid fever or cholera," may yet come to the front and secure further support.

*The Contagion Theory.*—Although clear and distinct instances of the direct communicability of leprosy from person to person are few and far between, and, from the nature of the disease, its latency and uncertain prodromata—difficult to prove, it appears to me that we cannot now deny its "contagiousness" in the sense that untainted individuals may occasionally become affected with the disease after being in close relation with lepers. As far as I can see there is no getting over Dr. Hawtrey Benson's case,<sup>6</sup> and as that careful physician remarks, "to ignore the evidence of contagion in this case, where the circumstances are so simple and so well authenticated, is indeed to strain scientific caution to its utmost limit, if not beyond it. . . . The proof of contagion afforded by this case possesses a force little short of that of a mathematical demonstration." I agree with him that "one such fragment of positive evidence carries more weight than a vast accumulation of negative evidence." In 1885, in his lecture on leprosy, Mr. Jonathan Hutchinson is reported to have said, "of course, if you are prejudiced in favor of its contagiousness, you can produce instances apparently in favor of it, especially if you reject a thousand negative facts in favor of one fact which seems to support it. I submit that no one who will read a record of the facts can ever believe that contagion can take place." There are other authorities, too, who, having made up their minds on the subject many years ago, are "of the same opinion still;" several, however, have seen reason to modify their views. Until a few years ago most of the Norwegian physicians disbelieved in the contagion of leprosy. Dr. Hansen, however, the discoverer of the bacillus, boldly asserted its infective character; and I found last year that Dr. Sand, of Trondhjem, and Dr. Kaurin, of Molde, have both come round to his way of thinking. The veteran Dr. Danielson, however, is still of the old opinion—for, as he told me, "in all his long experience with the disease he had never met with one single instance of contagion." Dr. Nickoll also has no belief in the contagion of leprosy, nor indeed in its heredity. Dr. Kaurin now considers that leprosy is not transmitted by heredity, although like Virchow and many others, he admits that there may be hereditary predisposition to contract the disease. He informed me that he had seen several cases, besides the one he has published, which point to direct contagion. Dr. Sand is of a similar opinion; and I learnt from him that he has known of two cases of servants—one at the Molde asylum, and one

at Bergen—having contracted the disease while in attendance on lepers. He knows, too, of many other instances which can be, at any rate, most satisfactorily explained by the theory of contagion.

Dr. Phillippo, of Jamaica, gave me, last year, his opinion as follows: "It is communicable by contagion. This has always been the opinion amongst most of the laity, and, with some reservation, amongst many of the medical profession. Of late years I have known some most undoubted cases of contagion, and yet there have been many instances of relatives who have for years lived in daily intercourse of the freest kind, as parents and brothers and sisters, who have not suffered, and a small number of those who undoubtedly have. . . . I know of cases where there was no hereditary disease in which one member of a family has taken it from another. In one case, the husband, a European, took it from the wife. In him it ran a rapid course, and he died before her, though she had it for years before him. I know of cases in which this disease has been taken from outsiders, and have heard of others in which it has been taken from the wet nurse."

It is interesting to observe that Dr. Phillippo is one of those authorities mentioned by Dr. Gavin Milroy<sup>7</sup> as being opposed to the view that leprosy is contagious.

Dr. A. R. Saunders (M.D., Lond., F.R.C.S. Engl.), one of the leading practitioners (for 14 years) of Kingston, Jamaica, has recently informed me that he has no doubt whatever as to the contagiousness of leprosy, and that he has under his care at the present time in Jamaica several cases which can only be explained by the theory of contagion. He ridicules the idea of a fish diet having anything to do with the disease.

Dr. Blanc, of New Orleans, states in the paper quoted, his belief, after a study of these forty-two and other cases, "that leprosy may be communicated from a leprosy to a non-leprosy person by means of a specific virus, which acts like a specific poison of syphilis, depending upon thin or denuded surfaces for its absorption, and which remains potent, very probably, for an indefinite period of time."

The doctors in the Sandwich Islands are all (and have been, with one exception, Dr. Fitch, report, Honolulu, 1886), believers in the contagion of leprosy; as are many of those at the Cape, in India, in the West Indies, and elsewhere. Dr. G. H. Fox, of New York,<sup>8</sup> indeed says, "Now it is generally admitted by those who have most carefully studied the facts of the case that leprosy is a contagious disease." He further remarks that "granting leprosy is contagious, we are forced to admit that it is so only to

a very limited extent." Most people will concur in this.

Some of the ablest observers are still keeping their minds open on the question. Dr. Beaven Rake writes that he has met with no case of contagion in Trinidad, but that he can bring forward many negative instances. His inoculation experiments on animals, too, have been so far unsuccessful—as were those which were formerly practiced on the human subject in Norway, in Mytelene, by Bargilli, and more recently in Sicily by Profeta. Even Arning's experiment on the convict at Honolulu, is, in Dr. Rake's opinion, not conclusive. This man, Keann, was inoculated September 30, 1884, by Dr. Arning, "after having previously made a most searching inquiry as to any leprosy taint in his family, and a close examination of his own body," which examination, says Dr. Arning, "satisfied me that, as far as I am able to judge, no trace of the disease could be found on him at that time." Dr. Beaven Rake's valuable "Report on the Trinidad Leper Asylum for 1888," has just been kindly sent to me by the author. In it, in reference to this inoculation, he says, "When, however, we come to examine this question dispassionately, what do we find? A man living on an island infested with leprosy was inoculated three years' ago with the disease and has now developed it. But in that time he may have acquired leprosy in a dozen different ways, in air, food, water, etc., or it may have been in his family. True, the man was ascertained as far as possible to come of a clean family, and he has been isolated in goal since the inoculation. Still, anyone who has attempted to take the statement of lepers will appreciate the value of family history, and in a country where leprosy is rampant are we sure that it can be shut out by four walls? I repeat what I said in my last report, that an experiment of this kind, to be scientifically perfect, must be performed in a country free from leprosy, and in an individual who has never left that country, and whose immediate ancestors have always stayed at home."

Mr. C. Macnamara, then of Calcutta, discussing in 1866 the Indian Reports on Leprosy in an able article in the *Indian Medical Gazette*, stated in addition to other arguments in favor of the view of its contagiousness: "(1. A large proportion of the civil surgeons in this presidency believe, from personal observation, that the disease is contagious. (2.) The instances quoted from this report can only be explained by supposing the disease to be contagious."

Any opinion, however, which was favorable to contagion prior to the year 1867 went for nothing, for in their celebrated and authoritative Report of that year, the Royal College of Physicians of London, made the sweeping statements, so often quoted, that: "The all but unanimous conviction

<sup>7</sup> In his report on Leprosy in the West Indies, 1873, p. 30.

<sup>8</sup> In his "Remarks on the Treatment of Leprosy," New York, 1885.

<sup>9</sup> Appendix to Report on Leprosy, Honolulu, 1886, p. 43.

tion of the most experienced observers in different parts of the world is quite opposed to the belief that leprosy is contagious or communicable by proximity or contact with the diseased. The evidence derived from the experience of the attendants in leper asylums is especially conclusive on this point. The few instances that have been reported in a contrary sense either rest on imperfect observation, or they are recorded with so little attention to the necessary details as not to affect the above conclusion." More than 250 replies to the interrogatories of the College Committee had been received from medical men and others located in the various leper centers, and a large majority of these were undoubtedly in the negative with regard to the communicability of leprosy from person to person. Some 32 or so, on the other hand, gave a more or less affirmative answer in reference to the question; and several qualified men actually cited cases in support of their views; *e. g.*, amongst others, Drs. Aquart, of Grenada; Manget, of British Guiana; Regnaud, of Mauritius; Jackson, Harris, and Messrs. Macnamara, and Rose, of India. On looking over the report, it is difficult to see why the opinions of these gentlemen, many of whom had been for years in charge of lepers, should have been, apparently, considered so unreliable and worthless, in comparison with the others. The College, it seems, did not modify its views for years; but in 1887 we learn that "the committee are quite aware that there is much difference of opinion respecting the communicability of leprosy, and that many colonial practitioners and inhabitants do not concur in the views expressed by the College in their Report in 1867."<sup>10</sup>

There is indeed, as the Committee now admits (April 7, 1889), "increasing evidence respecting the communicability of leprosy;" and it seems to me that we cannot ignore the cases reported, and the opinions formed upon them, by such qualified observers as Vandyke Carter in India, Petersen and Münch in Russia, Besnier, Vidal, Leloir, and Cornet in France, and by many others of large experience and of high repute in all parts of the world.

In point of fact, however, any circumstances whatever—however strong they may be—which apparently lend support to the contagion theory, so long as they occur in a country in which leprosy is prevalent, are liable to be laid aside with some such "begging-the question" remark as, that "after all it only amounts to this, that a person has become a leper in a place where the disease is endemic!"

In conclusion, I venture to express the opinion—after a somewhat extended study of the subject—that, with the facts at present at our disposal, it appears to be a pure assumption, unsupported by valid evidence, to say that leprosy can *only*

gain a footing in the human body *per unam viam*.

Dr. Gavin Milroy, the secretary of the committee which scouted the idea of contagion, said, after his visit to the West Indies, that "leprosy appeared to him to be neither more nor less contagious than scrofula." We have no reason to assume that it may not be introducible in as many ways, although, perhaps, with much greater difficulty. The problem will, possibly, be fully solved when we know the whole life history of the microbe which is characteristic of the disease.

### THE AMERICAN MEDICAL ASSOCIATION AND ITS RELATIONS TO PUBLIC HEALTH.

*Read in the Section on State Medicine, at the Fortieth Annual Meeting of the American Medical Association, June 27, 1889.*

BY N. S. DAVIS, M.D., LL.D.,  
OF CHICAGO, ILL.

Although the primary and potent influence that prompted the movement that resulted in the assembling of the Convention of delegates in the city of New York, May, 1846, to effect a permanent National organization of the profession of the United States of America, was the desire to elevate the standard of professional education and thereby increase the usefulness and honor of the profession; yet even that preliminary Convention did not pass without initiating important measures having a direct bearing on the interests of public health.

On the second day of that Convention, May 6, 1846, Dr. John H. Griscom, of New York City, offered the two following resolutions, which were adopted without opposition:

"Resolved, That a Committee of five be appointed to consider the *expediency*, and if deemed expedient, the *mode* of recommending and urging upon the several State Governments the adoption of measures for a registration of the births, marriages and deaths of their several populations.

"Resolved, That Mr. Lemuel Shattuck, of Boston; Drs. Jarvis, Dorchester, Mass.; Emerson, of Philadelphia; T. R. Beck, of Albany, N. Y.; and C. A. Lee, of New York, be a Committee to prepare a nomenclature of diseases, adapted to the United States, having reference to a general registration of deaths, to report to a future Convention."

By vote, the mover of the resolution was added to the Committee, as Chairman.

To constitute the Committee under the first resolution, the President of the Convention appointed Drs. J. H. Griscom, Alonzo Clark, Charles A. Lee, and James Stewart, of New York; and G. Emerson, of Philadelphia.

At the adjourned Convention, assembled in Philadelphia, May 5, 1847, both these Committees made able reports, that received the cordial sanction of that body. The report by the Committee on Registration of Births, Marriages and Deaths, contained a brief and pointed appeal addressed

<sup>10</sup> Vide "Leprosy Committee Report," R. C. P., July 15, 1887.

to the several State Governments, in favor of the enactment of such laws as would secure a general and uniform registration, and indicating the benefits to be derived therefrom. It also recommended the appointment of a Standing Committee to take general charge of the subject and annually report progress to the Association. It further recommended that the several State Medical Societies aid in urging the matter upon the Legislatures of their respective States. These recommendations were adopted, and after the Convention had resolved itself into the American Medical Association they were persistently prosecuted until there are but few States in the Union without laws of more or less efficiency on the important subject of vital statistics.

The important bearing of this movement made at the threshold of this National organization upon the interests of public health is more fully appreciated when we remember that it is only by a reliable registration of deaths and their causes in the population of any city or country that we are enabled to locate such deaths and compare their ratio to the population in one locality with another. This gained, the way is open for a careful comparison of the conditions of the soil, water, air, food, and personal habits, in the localities in which diseases and deaths prevail most, with those in which their ratio is lowest. And thus indication for the sanitary improvements come into the mind with all the clearness and force of well ascertained facts.

The Standing Committee to take general charge of the subject of registration, or vital statistics, as recommended in the report to which I have alluded, appointed by the Convention and approved by the Association after the completion of its organization, in May, 1847, consisted of the following members, viz.: Drs. J. H. Griscom, C. A. Lee, A. Clark, and John D. Russ, all of New York; and G. Emerson, of Penna.; R. D. Arnold, of Georgia; and Mr. Lemuel Shattuck, of Mass.

Probably the first attempt to make a general investigation concerning the hygienic and sanitary condition of the whole country was made by the Medical Department of the National Institute, at Washington, D. C., in 1845, when a Committee was appointed, consisting of Drs. James Wynne, Thomas Sewall, J. M. Thomas, Marcus Buck, and Dr. Baile, of the U. S. Navy. This Committee from time to time issued circulars addressed to members of the profession and others in different parts of the country soliciting information regarding the condition of the public health and the causes supposed to be capable of affecting it, in their respective localities.

At the second meeting of the American Medical Association, held in Baltimore, 1848, two members of the Committee, Dr. James Wynne, Chairman, and Dr. J. M. Thomas, attended as delegates from the Medical Department of the

National Institute, and presented a memorial, not only calling attention to the subject, but inviting the Association to appoint a committee to take charge of the further prosecution of the work. In their memorial it was stated that many replies to their circulars had been received and much information of more or less value obtained, but not sufficient to justify the publication of a formal report on so important a subject.

The memorial was received and referred to a Special Committee for consideration. At a subsequent stage of the meeting the Committee reported, recommending the appointment by the President of the Association of a "Committee on Hygiene," to consist of twelve members, and with power to fill vacancies in their own numbers. [See Transactions of the Association, 1848, pp. 38, 42, and 43.] The recommendation was adopted, and the President announced as members of the Committee on Hygiene, Dr. James Wynne, of Baltimore; Dr. Isaac Parrish, of Philadelphia; Dr. Charles P. Gage, of Concord, N. H.; Dr. Peter C. Gaillard, of Charleston, S. C.; Dr. John M. Thomas, of Washington, D. C.; L. P. Yandell, of Louisville, Ky.; Dr. John P. Harrison, of Cincinnati; Dr. Edward H. Barton, of New Orleans; Dr. Albert Smith, of Peterboro, N. H.; Dr. John H. Griscom, of New York; Dr. J. Curtis, of Lowell, Mass.; and Dr. Turner, of New Orleans.

Another subject of importance, and at least indirectly affecting the public health, received prompt attention at the same annual meeting, namely, the adulteration and deterioration of drugs. A long and very important paper on the subject was presented by Dr. T. O. Edwards, of Ohio, a member of the National House of Representatives,<sup>1</sup> which was responded to by a memorial to Congress urging the passage of proper laws for preventing the importation and sale of adulterated and worthless drugs.

It is thus seen that during the first year after the completion of its organization this Association had entered actively upon the work of promoting the public health in three directions, viz.: the securing of reliable registration of births, marriages and deaths; 2. the direct investigation of the causes of disease and the means for their removal; and 3. the securing of drugs of standard quality and purity. This third line of work was prosecuted so efficiently that Congress soon enacted the necessary laws for the proper inspection of all imported drugs, and they have continued in operation until the present time.

At the second annual meeting of the Association, which was held in Boston, May, 1849, the Committee on Hygiene, composed of twelve members, as already stated, made a brief general report on the subject of drainage, street cleaning, water supply, building and ventilation, nuisances,

<sup>1</sup> See Transactions 1848, pp. 38 and 391.

and disinfectants, and special reports on the sanitary condition of the cities of Portland, Concord, Boston, Lowell, New York, Philadelphia, Baltimore, Charleston, New Orleans, and Louisville; on the use of disinfectants in the Navy, and on the influence upon health of the introduction of tea and coffee in large proportion into the dietary of children and the laboring classes, making in all 224 pages of the volume of Transactions for that year. These special reports and papers present a great variety of facts and observations of the highest importance, and to students of sanitary science they afford the best indication of the status of sanitary interests in this country half a century since that can be found on record. This is especially true regarding the special reports on Boston and Lowell, by Dr. Josiah Curtis; on Philadelphia, by Dr. Isaac Parrish; on Baltimore, by James Wynne; on Charleston, by Dr. P. C. Gaillard, and on New Orleans, by Edward H. Barton. The report of Dr. Curtis gives a very interesting history of the sanitary measures and public hygiene of Massachusetts from its early Colonial settlement to the time he wrote, 1848, including a valuable summary of its vital statistics.

In addition to the full reports from the Committee on Public Hygiene, the Standing Committees on Medical Sciences, and on Practical Medicine, in their reports at the same meeting of the Association, gave many facts of much interest relating to public health, particularly in connection with the appearance of Cholera in New York and in New Orleans in December, 1848, and other epidemic diseases in various parts of the country.

The next annual meeting of the Association was held in Cincinnati, May, 1850, when the Chairman of the Committee on Hygiene, the late Dr. Josiah M. Smith, of New York, presented one of the most interesting and valuable reports on the "Sources of Typhus Fever and the Means Suited to their Extermination," that I have ever read. Regarding human or animal excretions as the chief source of typhus and typhoid fevers, he gives a very complete exposition of the composition and quantity of the excretions from the human body, including the exhalations from the skin and the lungs, and of the extent to which the walls, furniture and air of rooms, as well as the soil and water, may become so contaminated as to develop and propagate the essential causes of continued fevers. Besides this report of the Chairman, two special reports were made by other members of the Committee. One was made by Dr. Edward Jarvis, of Dorchester, Mass., on the "Sanitary Condition of Massachusetts and New England," and is an excellent supplement to the special report of the previous year, by Dr. Josiah Curtis. The other was by Dr. J. C. Simonds, on the "Hygienic Characteristics of New Orleans," and is a fitting complement to

the report of Dr. Barton the previous year. At the same meeting of the Association in the report of the Standing Committee on Practical Medicine and Epidemics, made by Drs. J. K. Mitchell, R. LaRoche, and Francis West, we have a very able and detailed account of the great cholera epidemic of 1849, and embodying facts worthy of the careful study of investigators and practitioners of the present time.

The annual meeting of the Association for 1851 was held in Charleston, S. C., at which further reports were made by the Standing Committees on Public Hygiene, and on Practical Medicine and Epidemics. It was at that meeting that the Standing Committees were abolished and a large number of Committees appointed to report on special subjects. The several States of the Union were divided into eight groups, and a Committee of three was appointed for each group, to report on the prevalence of epidemics and their causes. In the reports of these Committees at the meeting of 1852, in Richmond, Va., may be found valuable information concerning not only the epidemics, but also of the topography and general sanitary condition of the districts where the epidemic diseases prevailed, in most of the Eastern, Middle and Southern States.

At this meeting, also, a vigorous movement was commenced for improving the sanitary condition of ships carrying emigrants across the seas, and for compelling them to have on board competent surgeons to render proper care of such passengers as need their services. An able committee was appointed and instructed to memorialize Congress on the subject, and to enlist the influence of the several State Medical Societies in the same direction.

At each subsequent annual meeting, until 1859, the Committees on the Topography, Epidemics, and Vital Statistics of the several States and large cities made reports of such extent and value that they occupy not less than one-third of the pages of the several volumes of Transactions for those years. Experience had been demonstrating from year to year the impossibility of hearing in detail such an amount of material in the General Sessions of the four days allotted to each annual meeting, and hence the larger number of these reports, as well as those made regarding other departments of medicine, were read by title only and referred for publication.

To remedy this defect, the eminent sanitarian who is at present presiding over this Section of State Medicine, in the annual meeting of 1859, moved to so amend the By-laws that the General Sessions of the Association during the annual meeting should be limited to the morning of each day, and the afternoon should be devoted to meetings in a specified number of Sections. The plan was earnestly supported by the writer of this report and adopted by the Association.

It provided for five Sections, namely : 1. Anatomy and Physiology. 2. Chemistry and Materia Medica. 3. Practical Medicine and Obstetrics. 4. Surgery. 5. Meteorology, Medical Topography, Epidemic Diseases, Medical Jurisprudence and Hygiene.

These *Sections* were first organized and entered upon their practical work at the next annual meeting, which was held in New Haven in 1860. They have been rearranged and added to from time to time until their number has been doubled. But through all the changes they have invited, received and caused to be published valuable contributions relating to the public health every year. So true is this, that the annual volume of the Transactions of this Association from 1847 to 1882 contain the materials for a more complete history of the more important epidemic diseases that have prevailed in different parts of this country during the last half-century, with a synopsis of what had been put on record previously, than can be found elsewhere. Accompanying the numerous papers relating to epidemic disease is to be found a large amount of information concerning the topography, soil, water and meteorology of almost every State in the Union. The same series of volumes contain papers and reports from many of the most eminent members of the profession on almost every question relating to personal and public hygiene and vital statistics, whether in the city or in the country, on board of ships, or in camps, prisons, or asylums; not even omitting the consideration of foods and drinks. And through it all there is evidence of a constant and ever increasing demand upon the various legislative bodies, State and National, for the enactment of such laws and municipal regulations as would remove all those unsanitary and destructive influences resulting from density of population and neglect of cleanliness, ventilation, drainage and water-supply. All these efforts in the National body were reflected back through their delegates to the State and more important local societies. The effect upon the legislative bodies has been slow, but constantly cumulative. At the date of the organization of this Association, Massachusetts was the only State having a law for the registration of births, marriages and deaths, which had been enacted in 1842, and had been imperfectly executed. Until that period even the statistics of mortality were chiefly obtainable only from the records of the various cemeteries belonging to the larger towns and cities. Twenty-five years later Dr. Joseph M. Toner, in a statistical report on Boards of Health of the United States, records the existence and regular organization of Boards of Health in more than *one hundred* cities and towns, and State Boards in seven States, namely, Massachusetts, Rhode Island, Virginia, Louisiana, California, Michigan and Minnesota. (See Proceed-

ings of Am. Public Health Association, Vol 1, p. 499, 1873.) Laws for the registration of vital statistics had been enacted in a larger number of States, and much influence had been gained both in the profession and outside of it, in favor of the establishment of a National Health Bureau. Indeed it was this rapidly increasing number of health boards and sanitary measures under the diverse legislation of many States that led directly to conferences among the Health Officers engaged in practical work, for the purpose of securing greater harmony of action. These, commenced in 1872, led in the following year, 1873, to the permanent organization of the American Public Health Association, and its subsequent career of usefulness. Later in the same year the severe epidemic of cholera prevailed throughout the Southwestern States, followed by an equally destructive epidemic of yellow fever in 1878-79, both of which served to greatly increase the action of legislative bodies, whether National, State or municipal, on sanitary measures. A National Board of Health was organized under a law of Congress, and although it proved of temporary duration it was followed by such an enlargement of the powers and duties of the U. S. Marine-Hospital Service as makes it, in some degree at least, a National health department, without the name. And State and local Boards of Health have become organized in nearly all the States and commercial cities of the country, and are annually increasing in their efficiency and harmony of action. In the accomplishment of these results, this Association with its constituent organizations, the State and local Medical Societies, has been not only the primary and chief force in moving legislative bodies to action on measures for protecting and improving the public health; but it has been steadily accomplishing an equally important work in educating the profession itself to a better appreciation of the nature and importance of preventive medicine, or sanitary science. And so far from having completed its work in either of these directions, it has only made a fair beginning, and improved its methods and implements for more efficient progress.

A knowledge of the causes of disease, their modes of development, the conditions under which they are capable of maintaining an active existence, and their *modus operandi* in the human system, must constitute the basis of preventive medicine and the only reliable guide to the adoption of such sanitary measures as will practically limit the prevalence of diseases and permanently lower the ratio of mortality wherever they may be instituted. That knowledge, which consists in the simple discovery or identification of the specific cause of a disease and its assignment to its proper scientific position among the myriads of organic germs, or in the long list of chemical products, is not sufficient for the successful prose-

cution of measures for the protection of the public health. Such identification is but a single item, though a very important one, in the series of facts needed for a successful warfare against the enemies of human health and life. Every living pathogenic germ must have its own pabulum or food and certain physical conditions of temperature, moisture, etc., for its development and propagation; and experience has shown that in a majority of instances measures for the removal of the pabulum, or for controlling some of the essential conditions, are more efficient in preventing its development than any measures for the direct destruction of either the living germ or the chemical ptomaine.

Therefore it becomes as necessary for the sanitarian to identify the materials in the soil, the water, the air, and in the living body, capable of feeding pathogenic germs or entering into the formation of ptomaines, as to discover the specific disease-producing agent itself. To cover the whole field of investigation successfully it is necessary to have the coöperation of all classes of workers in the profession. The carefully recorded observations of the general practitioner and of the specialist in their direct dealings with diseases and injuries, fixing the dates of their occurrence, progress and results, are as necessary to the proper understanding of the causes of disease and the conditions under which they are developed as is the most skillful work in the laboratories of the microscopist and the chemist.

It is only by the coöperation of observers occupying different standpoints of observation that the investigation of etiological subjects can be made complete. Consequently there is no medical organization in our country better adapted for the prosecution of such work than this Association, with its Sections covering all departments of medical science, and its JOURNAL through which the work of each becomes quickly distributed to the whole.

I trust, therefore, that this Section will not only continue a vigorous prosecution of investigations pertaining to the public health and preventive medicine, but will also so systematize the work as to render it more reliable and complete.

## MEDICAL PROGRESS.

**PHLEGMONOUS AND GANGRENOUS PROCESSES IN DIABETES.**—Although the occurrence of purulent and gangrenous processes as the result of diabetes has been known for a long time, yet but little is known regarding the etiology, diagnosis and treatment of these processes. Formerly their etiology was sought in a specific action of sugar upon the tissues. Since König it is universally

believed that especially diabetic phlegmon is the result of an infection the same as other phlegmons. As regards diabetic gangrene, Schüller is of the opinion that it is caused by acute arteriosclerosis and previous inflammations induced by pus-cocci. For the diagnosis of diabetic phlegmon the following points seem to be of importance: Development from an insignificant injury, its combination with gangrenous processes, and its obstinacy.

Regarding the diagnosis of diabetic gangrene, its occurrence in still robust, relatively not old people, consequent upon some slight injury or inflammation, and its painfulness, are significant.

Concerning the treatment of phlegmonous and gangrenous processes, MAX SCHÜLLER (*Berlin Klin. Wochenschrift*, Nos. 47, 48, 49, 1888), advises an early surgical intervention, and warns against delay for the purpose of a previous general diabetic treatment; he considers local, surgical, especially antiseptic treatment at the beginning as more important than the former. The greatest stress must be laid upon the treatment of the phlegmon itself, and its rapid and easy spreading must be fought against energetically with extensive incisions, draining and rinsing, and baths with antiseptic fluids, even more energetically than in common phlegmons in patients not affected with diabetes. In diabetic gangrene the conditions are more unfavorable. Local treatment must likewise be strictly antiseptic. If the physician succeeds in this way in obtaining a line of demarkation or in confining the gangrene, the part affected must be removed from the healthy portion with strictest antisepsis; if the gangrene can not be checked, at least the patient's life may be saved, as König has shown, by antiseptic amputation.

From a prophylactic standpoint the author advises the strictest attention to even the slightest injuries, in view of the great vulnerability of diabetic patients and their tendency to phlegmonous and gangrenous processes.—*Wiener Medicinische Wochenschrift*, No. 17, 1889.

**REGARDING GLANDULAR NERVES.**—In examining the tongue of a rabbit after injection with methyl-blue, RETZIUS (Verh. d. Biol. Vereins, of Stockholm, I, No. 1) found in the vicinity of the papilla foliata the little glands in that region overspun with nerve fibres colored a beautiful blue. Alongside the glands he saw little nerve-trunks whose axis-cylinders were blue, and from these single fibres branched off that ran toward the alveoli of the gland to divide again into branches there. These nerve fibres were varicose and so thin that they had to be regarded mostly as end fibrilli. They surrounded the alveoli of the gland in all directions like nooses, lay evidently close upon the membrana propria, and formed a rich network closely surrounding the alveoli. In

some alveoli it seemed to Retzius that these fibres ended in cells, but he could not discover them entering these cells.

Through this observation we have progressed a step in the important question of the glandular nerves, inasmuch as we have here the last branches of the glandular nerves on the alveoli of the glandular cells, and these nerve-fibres proved very abundant and fine.—*Centralblatt für Physiologie*, No. 2, 1889.

ON THE INDICATIONS AND PROGNOSIS OF THE OPERATIVE TREATMENT OF ABDOMINAL TUMORS.—In a paper published in *Orvosi Hetilap*, No. 48, 1888, W. TAUFFER, of Budapest, says: "Every movable ovarian tumor, of at least the size of a fist, if diagnosed with certainty, should be removed, and the sooner the better. Ovarian tumors located between the ligaments, deep in the pelvis, are so dangerous to approach (because of their close proximity to large vessels, the urethra, etc.) that their removal should be postponed until, rising from the pelvis, they begin to distend the abdominal walls and have thus become more accessible. Neither youthful or advanced age, nor malignant character of the tumor, kidney or heart affections, tuberculosis, extensive adhesions, acute peritonitis or a purulent character of the swelling should be considered an obstacle to the operation if the life of the patient appears to be endangered, and an improvement by the operation seems possible."

Despite these comprehensive views on the indications for operation, Tauffer lost of 172 ovariectomies (in ten of which supra-vaginal amputation of the uterus was necessary because of complicated conditions) only eighteen, *i. e.*, ten (4 per cent.), seven of these (4 per cent.) from sepsis.

The indication for ovariectomy Tauffer puts as follows: 1. Pathological changes in the position of the ovaries if causing acute symptoms and not curable otherwise. 2. Complete absence on deficient development of the uterus with normal ovaries, if ovulation causes intense pain. 3. Such diseases of the uterus as influenced by ovulation, heal after cessation of the latter (like intra-mural and some subserous myoma, fungus growths of the endometrium constantly returning, membranous dysmenorrhœa, many retroflexions not to be cured in any other way, etc.). 4. Chronic inflammation of the ovaries and their surroundings in cases where the entrance of blood accompanying evolution keeps up and constantly renews the inflammation. 5. Such acute diseases of the nerves as seem to be connected with ovulation and menstruation.

The thirty ovariectomies and salpingotomies made by Tauffer passed off without a fatality.

The radical treatment of tumors of the uterus he considers indicated: 1. In dangerous hæmorrhages which cannot be cured in any other way.

2. In symptoms of pressure which endanger the life of the patient, for instance, considerable pushing upward of the diaphragm, horizontal position of the heart, pressure on the large vessels, danger of incarceration, unbearable pains, etc. 3. If the tumor is growing rapidly. 4. If any complication dangerous in itself exists, or the vitality of the patient is sinking. Each of these conditions indicates the advisability of an early operation. In fifty-one cases of hysterotomy Tauffer had twelve with fatal results, *i. e.*, a mortality of 22.2 per cent. Regarding the treatment of the pedicle, Tauffer is a partisan of the extra-peritoneal method. In thirty-five other cases, only explorative incisions were made, or after opening the abdomen such adhesions of malignant tumors to the peritoneum or the intestinal walls were found as to make extirpation impossible; of these thirty-five cases, twenty-one terminated fatally sooner or later, whilst fourteen were cured by the operation.

Finally Tauffer mentions seven laparotomies with the following indications: Ancient irremediable inversion of the uterus; ileus caused by carcinoma of the intestines; twice extra-uterine pregnancy at the end of the pregnancy; twice hydronephrosis, and once loosening of adhesions which held the uterus in a retroflected position.—*Centralblatt für Gynäkologie*, No. 20, 1889.

A CASE OF HEMISYSTOLY.—DR. DEHIO demonstrated before the Medical Faculty of Dorpat sphygmographic courses taken from the radial artery and the neck veins of a patient with heart disease, in whose case there had been diagnosed an insufficiency of the mitral with grave compensatory disturbance and secondary relative insufficiency of the tricuspid valve in consequence of the dilatation of the right ventricle. Patient suffered from grave engorgements in the course of the great circulation, general dropsy, ascites, hydrothorax, orthopnœa, and during the last week of his life the well-defined symptoms of hemisystole of the heart, 80-76 contractions of the heart per minute could be distinctly counted by the aid of the stethoscope, but on the radial artery, as also on the carotid, just half as many pulsations (40-38) could be felt, so that there were two systolic and two diastolic tones for each perceptible arterial pulsation. Besides the systolic tones systolic murmurs could be plainly heard at the apex and at the lower end of the sternum. Simultaneously pulsation was plainly noticeable at the veins of the neck. Pulsation in the liver could not be established because of the ascites. The tracing upon the radial artery shows conclusively that this was a case of alternating pulse, a low pulse-wave between two high ones being distinctly visible in the descending portion of the curve; to be sure, this spot had become so small that the palpating finger could no longer feel it.

The tracing from the neck veins, on the other hand, show plainly two positive pulse-waves following each other rapidly, and separated by a longer pause from the next pair (pulsus bigeminus). The first wave of each pair corresponds with the perceptible radial pulse, the second is also in the neck veins, clearly shorter and almost always lower than its predecessor; only during expiration, when the obstruction in the neck veins became especially severe, the second wave was for a few days just as high as the first of the twin waves, or even a little higher.

This observation confirms the view advanced by Fränzel that the so-called hemisystole of the heart must be regarded as the highest stage of the pulsus bigeminus, during which the second wave of the twins becomes so small that it is no longer perceptible in the arteries of the great circulation. That the right ventricle produces alternately a strong and a weak pulse-wave the same as the left ventricle and isochromally with the latter, is demonstrated by the curves exhibited. A hemisystole as understood by Leyden, where the two ventricles act independently from each other, so that the right one within a given time contracts twice as often as the left, certainly did not exist in this case.—*St. Petersburger Medicinische Wochenschrift*, No. 18, 1889.

**A CASE OF HEART THROMBOSIS IN MYOCARDITIS FIBROSA AFTER SCARLET FEVER, AND IMBEDDING OF A PORTION OF THE LEFT VAGUS IN CALLUS CONNECTIVE TISSUE.**—SOMMER reports in the *Charité Annalen*, 1888, the case of a boy 10 years old who, nine weeks after recovery from scarlet fever, was taken with symptoms which led the author to suppose a hæmorrhagic nephritis with disease of the heart muscle. Later on symptoms of consolidation above the left lung, œdema of the legs and constantly diminishing diuresis occurred, and the heart symptoms became prominent. The examination of the heart when the boy was first received showed an extending of dullness toward the right, extending 2 cm. beyond the sternal line. The apex beat lies in the sixth intercostal space. In the course of the disease the pulse became alternating, greatly accelerated, 136–144–150, easily suppressible. Death ensued with symptoms of heart failure. At the post-mortem the heart was found to be greatly enlarged, both ventricles being much dilated with numerous parietal thrombi. The myocardium was largely replaced by dense connective tissue. Embolic infarcts in lungs, spleen and kidneys. No nephritis. The left vagus is surrounded by coarse fibrous tissue which originates from caseous and calcareous lymphatic glands. The microscope showed numerous granular cells, indicating degeneration in the compressed portion of the vagus. Supported by the investigations of Wasilief regarding the trophic relation of the vagus to the

heart muscle, Sommer supposes the changes in the heart to have been caused by the scarlatina and the partial degeneration of the left vagus.—*Centralblatt für Klinische Medizin*, No. 20, 1889.

**FORMATION OF PTOMAINES AND TOXINES BY PATHOGENIC BACTERIA.**—In a report to the Royal Academy of Sciences in Berlin, L. BRIEGER calls attention to the interest which attaches to the alkaloids produced by pathogenic bacteria, and makes public the results which he obtained by examination of the cultures of typhus bacteria on freshly peptonized blood albumen. He found in it neuridin ( $C_8H_{11}N_2$ ), which is isomeric with cadaverin; furthermore, mydin ( $C_8H_{11}NO$ ), which he had found so far only once in preparing human bodies. This ptomaine forms a picrate (melting-point  $195^{\circ}$ ) crystallizing in broad prisms, a chlorhydrate crystallizing in colorless little plates, an easily soluble chloro-platinat; it reduces a gold solution immediately, as also a mixture of chloride of iron and cyanide of calcium and iron. The free base has a strong alkaline reaction, and the smell of ammonia. Besides these two ptomaines the author obtained several times an extremely poisonous toxine which causes severe purging, sometimes also bloody urine, but has not been examined yet accurately. The author calls attention to the surprising circumstance that no ptomaine causing inflammation or necrosis could be separated from the typhus cultures. Finally he mentions that milzbrand bacilli have an oxidizing effect and produce some methylguanidin from creatin; but this occurs only when these bacilli are cultivated in bouillon containing peptonized blood albumen; in pure bouillon cultures another ptomaine originates which is not well known yet.—*Centralblatt für Physiologie*, No. 3, 1889.

**THROMBOSIS OF THE CAVERNOUS SINUS.**—PROF. NOTHLAG recently related a case of which the diagnosis was thrombosis of the cavernous sinns. (*Rev. Gén. de Clin. et de Therap.*, No. 26). The patient, aged 70, three years ago suffered from severe pain on the right side of the head, resembling neuralgia of the fifth nerve. Later there occurred diplopia and strabismus, which afterwards was succeeded by immobility of the eyeball. There is now closure of the right eye, œdema of the upper eyelid and right cheek, increase of temperature of that side of the face, and attacks of tic douloureux; anæsthesia involving the same region and also the tongue, conjunctiva, and cornea; vascular injection of the conjunctiva; intense keratitis and iritis. These symptoms referable to involvement of the fifth nerve and all the ocular nerves suggested a localized lesion at the base of the brain and were most likely due to cavernous thrombosis, caused probably by localized chronic meningitis rather than a tumor.—*The Lancet*, July 6, 1889.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Duglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JULY 27, 1889.

THOMAS KEITH ON FIBROIDS OF THE  
UTERUS.

In the present number of THE JOURNAL will be found a very comprehensive article by Dr. Apostoli, of Paris, on "The Treatment of Salpingo-ovaritis by Galvanism." In this connection it is very interesting to notice the high estimate in which Apostoli's treatment of fibroids of the uterus is held by so eminent an abdominal surgeon as Mr. Thomas Keith, as advanced by him in an article in the *British Medical Journal*, of June 8, 1889.

Dr. Keith, in the beginning of this article, deals with the assertion advanced by many of the opponents of electricity, to the effect that Apostoli's method is nothing but the revival of an old process, by giving the information that he was an assistant of Sir James Simpson at the time the latter was experimenting with the "so-called 'discussion' of uterine and ovarian tumors," and that now he "doubts if any electricity got into the body at all by the old methods, and, if this did so happen no good could have come of it for the interrupted current was always used."

Since those days he has carefully watched the many attempts to introduce electricity for the treatment of uterine tumors, but there was nothing to encourage him to try any of them. Drs. Kimball and Cutter certainly cured some, he thought, but he has too lively an impression of the risk of inserting large needles through the abdominal wall into the tumor to think of adopting that method. Dr. Keith's watching brought its reward, however, for he says:

"The only treatment not surgical worth speaking about that I have seen do any good, and which at the same time, is one free from danger to life if the treatment be undertaken by one who has respect for a strong electrical current, is that brought before us by Dr. Apostoli. If any one should have held on firmly to hysterectomy it is myself, for my results after it are better than any other. I have, however, thrown over all surgical operations for this new treatment, and the longer I follow it the more am I satisfied."

"To the surgeon, no doubt, hysterectomy is the good and simple plan. He may have his bad quarter of an hour at the operation, but then he has practically done with the case, and he gets his result quickly, sometimes more quickly than he cares for. If the patient recover there is pleasure all around; if things go badly and the patient die, he bewails his bad luck, as it is called. . . . waits a little, and then, though rather unwillingly, does another. He resents any other treatment than that by the knife. He especially resents Apostoli's treatment of fibroids by electricity, for the result is long in coming; it is a slow treatment, requiring great patience, great tenderness of manipulation and much thinking. . . . But with patience the result is certain. . . . There is no mutilation, a thing abhorrent to most women. . . . It puts a woman with a fibrous tumor, who suffers much, into the position of a woman with a fibrous tumor who does not suffer or may be even unaware of its presence. It does not bring about the disappearance of the tumor, or it does so very rarely, but the size is lessened more or less—one-half, one-third, two-thirds. . . . Tension is taken off everywhere, all around, and bladder irritability from pressure, a common cause of distress, is relieved. In a word, the woman is made well, her whole life is changed. All this can be done without danger to life, and if there be pain during the time the current passes the fault is in the operator. What more does a reasonable woman who has suffered much desire or need?"

"What have those to offer in place of all this who have so bitterly opposed this treatment, who with unlimited material stand aside and will not take the trouble to investigate the matter for themselves, but wait till someone else does it for them, who make only an outcry if by chance they hear of any accident during the progress of the treatment of any case, and who go frantic over the rumor of a death, or worse still, who proclaim they know of deaths that never happen? These men have absolutely nothing whatever to offer in the bad cases, and only hysterectomy in such tumors that will come out more or less easily, so as to be treated by the extra-peritoneal method of operating. I have seen not a few cases of bad bleeding fibroids since I came to London, almost everyone had consulted one or other surgical authority on the subject of operation. These were invariably told that nothing would do them any good but the removal of the tumor; but in their special case the local difficulties were too great, or they had let their strength go down too far for such an operation. The very feeble and bad cases, with masses of tumor blocking the pelvis, with absence of cervix, and opened-out broad ligaments, would seem to be

let alone. Hysterectomy then, at best, would appear to be a most doubtful remedy for a certain number of cases, and these not of the worst sort. On the other hand, the worse the case, the more feeble the patient, the greater the loss of blood, the more marked is the result of electrical treatment. Given a woman with a large bleeding fibroid, blanched almost to death from years of hæmorrhage, and see her some months after this treatment is completed, you would scarcely recognize her, the improvement is so great."

In an experience with his method in the treatment of a large number of cases, Dr. Keith has to mourn the loss of but one life, and of this he says:

"I do not say that the treatment was of itself the cause of death, which, I am satisfied, need not have happened; and in this I am borne out by the opinion of the patient's brother, a medical man. . . .

"The old spirit that at one time would have no abdominal surgery still unfortunately lingers amongst us. Electricity in any form, when applied to the cure of disease, is set down as pure quackery by many medical men, simply because they know nothing about it, and won't take the trouble to learn for themselves what to many is rather a hard study. . . .

"What I now plead for is that, for a time, all bloody operations for the treatment of uterine fibroids should cease, and that Dr. Apostoli's treatment, as practiced by him, should have a fair trial. Those who have hitherto most resisted the introduction of electricity are the surgeons who are the best competent to carry it out. They are accustomed to manipulate in the pelvis, and they will not make mistakes in the diagnosis, or make them as seldom as it is possible to do. Hysterectomy, remember, which is performed every day for a complaint that rarely of itself shortens life, kills every fourth or fifth woman who is subjected to it. This mortality must cease; it is not a question of surgery, it is a question of humanity. Every time that any disease can be cured without resorting to a bloody operation such as hysterectomy, progress is made in our art, and there is a gain to humanity, while surgery is the better for being purged of a deadly operation. It may seem strange to some that after the results I got in hysterectomy—results that almost made it justifiable—I should now begin to throw stones at the operation instead of trying still further to improve upon it; and but for Dr. Apostoli, I would now be doing so. I would give something to have back again those sixty-four women that I did hysterectomy for, that I might have a trial of Dr. Apostoli's treatment upon them; and I would give something never to have had the wear and tear of flesh and spirit that these operations cost me, for in scarcely one of them was the operation simple.

"I have said my say, and it must not be forgotten that the opinion here expressed as to the value of Dr. Apostoli's treatment is not that of an unsuccessful surgeon, but is the deliberate opinion of one who was the first to lower to a minimum the mortality that so long followed abdominal surgery, and who, by the best results in hysterectomy—results that Dr. Playfair is pleased to call almost phenomenal—still retains the position."

#### INSANE ASYLUM INVESTIGATIONS.

Recent events, too familiar to our readers to call for special mention, have set in motion one of those periodical waves of popular distrust in regard to the treatment of the insane in public institutions, which from time to time sweep over our country, leaving behind them some wrecked reputations, but too often, accomplishing little but destruction. While the excitement lasts the innocent are apt to suffer with the guilty; when it subsides things settle back into very much their former condition. We do not propose, at present, to discuss particular cases, but to suggest some general considerations which it seems to us well to bear in mind when such charges are made.

In the first place, there is no class of cases in which the maxim that a man is to be held innocent till he is proved guilty, is more applicable than this. The Superintendents of asylums for the insane, as a class, are by no means inferior to the average of our profession, either in attainments, character or disposition. Their position exposes them to constant assaults upon their reputation. No degree of humanity or tact will protect them from charges founded in the delusions or malice of their patients, and those who are most faithful and vigilant in guarding against abuses and enforcing discipline are most certain to incur the ill-will of lawless and vicious subordinates. Accusations coming from such sources may demand investigation, but they should be looked upon with suspicion, and if they are eagerly caught up and assumed to be true by the public, men who value their reputation will be likely to seek some other employment. Even the much-abused attendants are entitled to the same charity. In all well-regulated institutions they are selected with great care among numerous applicants; they are carefully instructed in their duties, and whatever may be the shortcomings of some of them, it is safe to say, that as a class, they are caring for the unfortunates under their charge with more skill and patience than most of their critics would exercise in their place.

In the second place, when abuses are discovered, the responsibility should be placed where it belongs. If an institution of this kind is made a part of the spoils of partisan politics, if its funds are used to enrich mercenary politicians, and its offices to reward their heelers, the community

which allows such a state of things has no occasion to be surprised or shocked if its insane are crowded into insufficient and unsafe quarters, if they are hungry and naked, if they are neglected and abused by incompetent and vicious attendants. The guilt is not confined to those personally concerned in such abuses, it is shared by those who, actively or passively, have abetted the system which gave them their opportunities for mischief. To rest content with their punishment while the system remains unchanged would be merely setting another set of wolves to watch the sheep. It may be said in general that attempts to combine a poor-house and an asylum for the insane under the same management, have not usually had very satisfactory results, at least, so far as the latter is concerned. The standard is apt to be set by the accommodations and treatment allotted to paupers, and whether sufficient for them or not, it is not suited to the needs of the insane.

Finally, it is, in our opinion, questionable whether, in some instances, the well-meant efforts of friends of the insane to improve their condition have not had results which were not foreseen nor desired. The abolition of mechanical restraint, for instance, has been advocated in some quarters with an enthusiasm which seemed to make it an end to be obtained at any cost, rather than a means of securing the comfort and improvement of the patients. It might be imagined, from some of the accounts which have been published, that interference with the personal liberty of the insane was the cause of all their misconduct, and that an asylum for their care and treatment would run itself, to the satisfaction of all concerned, if the patients were only allowed to do as they pleased, without interference, except by way of friendly suggestion from physicians and attendants. Now the fact is, that some of the *insane* are no more amenable to reason than the *sane*. Tact, patience and kindness will work wonders in many cases, but there are those who can only be restrained from mischief by physical force in one form or another, and others with whom the only alternative is fear. Attendants are expected to control their patients. Their reputation, and the comfort and safety of their inoffensive patients, as well as their own, depend upon their keeping the disorderly and violent in subjection. To struggle, for hours at a time, day

after day, with a powerful man, or to be continually subjected to assaults from one who understands and presumes upon his impunity, is a pretty severe strain upon the mildest disposition, and, though unfortunate and wrong, it is not strange that human nature does not always endure the trial. We have reason to think that in some cases where the use of mechanical restraints has been forbidden in the quiet and order of the wards, so gratifying to officers and visitors, has been due in part, to the clandestine use, by attendants, of still more objectionable means.

The proper care of the insane is a work of sufficient difficulty to task all the resources of the best mind. Routine and inflexible rules, whether self-imposed or dictated from without, will often stand in the way of the best results. The physician may be helped by the suggestions or example of others, but if he has not sufficient intelligence and humanity to be trusted with the care of his patients, the probability is that little will be gained by hedging him about with vexatious restrictions; if he has, they are more likely to do harm than good.

It is well that those who have the care of this most unfortunate and defenseless class should feel that abuses and neglect cannot pass unknown or unpunished, but public opinion, in such cases, should be not only a terror to evil doers, but a praise to them that do well. Nothing can be, in the long run, less for the interest of the insane than indiscriminate condemnation of all who are engaged in caring for them.

#### EDITORIAL NOTES.

##### HOME.

THE AMERICAN RHINOLOGICAL ASSOCIATION will hold its Seventh Annual Meeting at Chicago, Aug. 28, 29 and 30. The Committee on the Examinations of the Inmates of Insane Asylums will make their report on "The Relations of Rhinal Inflammations to Mind Affections" at this session.

LEPROSY IN NEW ORLEANS.—A despatch to the daily papers, dated July 21, says: Investigation of the case of the young man, James Kavanaugh, in Algiers, who is suffering from tubercular leprosy, discloses the fact that his companion and associate a few years ago was a man named

Mallegar, who resides in the Third District, near the mint. This man was afflicted with the loathsome disease and Kavanaugh was constantly in his company, at times ate with him and drank out of the same vessel that he did, and it is evident that he contracted the disease by so doing. There are now under observation several suspicious cases which the Board of Health will send a corps of experts to Algiers to inquire into.

THE STATE UNIVERSITY OF TEXAS will soon have a fine building for its Medical Department. Galveston recently appropriated \$25,000 towards its erection.

DR. HENRY M. HURD, of Pontiac, Mich., now Superintendent of the State Lunatic Asylum at Pontiac, has been appointed Superintendent of the Hospital of Johns Hopkins University.

THE TREATMENT OF SUNSTROKE.—Dr. Wm. F. Waugh contributes to *The Dietetic Gazette* the following: In true sunstroke we have succeeded best at the Medico-Chirurgical Hospital by giving antipyrin internally or by hypodermic, in doses up to 30 grains, and applying ice energetically, externally and in the rectum, until the temperature descended to the level of safety. The great majority of cases, however, are really of exhaustion, due to heat and free drinking, with consequent perspiration and loss of salts. Small doses of brandy, ammonia, wine of coca, selecting a really efficient variety, and hot coffee are efficacious at first; followed by a hot bath, hot beef-tea, quinine, or Huxham's tincture. The use of ice-water gives rise to unquenchable thirst. Free imbibition of fluids causes loss of appetite. An excellent beverage for Summer is thin oatmeal gruel, with salt, but no sugar, taken as hot as can be swallowed.

TENNESSEE MEDICAL EXAMINING BOARD.—*The Times-Register* says: Tennessee has now a Medical Examining Board, and the Governor with singular good judgment has given to the State Medical Society the privilege of recommending three members of this Board, he to nominate the fourth regular practitioner. Elected in such a manner the Board is likely to be both competent and just.

#### FOREIGN.

IN SPAIN the Sociedad Española de Higiene

has formulated an appeal to the authorities asking for the establishment of a public system of disinfection, and the rigorous enforcement of the measures for that purpose approved of by the Vienna Congress of Hygiene.

IN GREAT BRITAIN the recent election to fill the vacancies in the College of Surgeons caused by the retirement of Sir James Paget, Mr. Hulke and Mr. Heath, resulted in the return of the two latter gentlemen, who sought reëlection, and Mr. Howse. At the last meeting of the British Laryngological and Rhinological Association, Dr. Philip Smyly, of Dublin, was elected President for the coming year, and the following gentlemen were elected Honorary Fellows of the Association: Professor Voltolini, Breslau; Professor Massei, Naples; Dr. Solis-Cohen, Philadelphia; and Dr. Fanvel, Paris. Hundreds of applications have been received for the position of Director-General of the Naval Medical Reserve. *The Provincial Medical Journal* says: A boy recently died of hydrophobia near Bradford—at least so it was said at the Coroner's inquest; but, strange to say, the dog which inflicted the bite also appeared at the inquiry, sound and healthy, from which we draw the conclusion that the boy did *not* die of hydrophobia. The British journals are strongly advocating the study of shorthand by medical students.

PROF. FRANCIS CORNELIUS DONDEERS, the eminent ophthalmologist, died recently at the age of 71.

AN INTERNATIONAL COURTESY.—The *British Medical Journal* pays a well deserved compliment to Dr. John S. Billings, reciting the valuable work which he has accomplished and the honors to which he has attained. It is gratifying to the American profession that such an able man is numbered in its ranks, and to know that he is so well appreciated in other lands.

PROFESSOR BILLROTH completed his sixtieth year on April 26, but was absent from Vienna at the time. On his return the students and his friends prepared a splendid ovation for him. Dr. Sjsrgerwitch, Minister of Public Instruction of Servia, presented the Professor with the Grand Cross of the St. Sava Order, and the Vienna students presented him with a medal which bore on one side his portrait, with these words: *Theodorus Billroth, ætatis sue 1x*; on the other: *Medico*

*artifici, viro optimi pictate conjuncti discipuli et sodales.* Professor Billroth was also the recipient of several other distinctions on this occasion.

**A PHILANTHROPIC PRINCE.**—The Duke Charles Theodore of the house of Bavaria is well-nigh worshiped by the poor peasants about Meran, in the Austrian Tyrol, for his goodness of heart and his actual services in their behalf. They call him "the good Duke-Doctor." He annually offers his gratuitous help to the poor who have need of eye treatment. It is stated that this spring he, with an assistant surgeon, saw 1,091 cases, many of them surgical. Cataract operations to the number of sixty-eight were done, all of them primarily successful.

This is, indeed, princely conduct, and a remarkable improvement upon the kind of surgery done by many of his illustrious ancestors, whose work with cutting implements was chiefly limited to the field of battle; they were destructive in their intents and tendencies, he is reconstructive. And so he may be considered to mark a new era among the hereditary rulers of Europe.

## SOCIETY PROCEEDINGS.

### AMERICAN MEDICAL ASSOCIATION.

#### Fortieth Annual Meeting. Report of Sections.

(Concluded from page 68.)

#### *Section on the Practice of Medicine, Materia Medica and Physiology.*

FOURTH DAY, JUNE 28, 1889.

DR. J. G. TRUAX, in his paper on *Ulcerative Endocarditis*, reported six cases only two of which were diagnosed before death, thus demonstrating the difficulty in diagnosis. The writer was inclined to believe that the disease was due to microorganisms, though such had not been discovered.

DR. MARY E. BALDWIN read a paper entitled *Stomach Rest and Cleanliness*, in which, with the reports of cases, was demonstrated the benefit derived from the method of washing out the stomach and the judicious management of diet. Measures were recommended for similar troubles in children.

DR. W. S. WATSON read a paper on *Addison's Disease*. After a thorough review of the pathology and etiology of the affection, a case illustrating its symptomatology and course was presented

to the Section by the essayist. A post-mortem had been obtained and an excellent specimen, demonstrating the changes in the supra-renal capsules, obtained.

#### *Section on State Medicine.*

FIRST DAY, JUNE 25, 1889.

DR. P. H. MILLARD, of Minnesota, Chairman, presented the *Report of Committee on Uniform Medical Legislation in the United States*.

Dr. Millard's subject was *The Legal Restriction of Medical Practice in the United States*. He finds this country sadly in need of good medical legislation. North Carolina was the first State to enact anything like satisfactory medical laws. He praised the State of Illinois for the work done in this direction, ascribing great credit to the efforts of the Secretary of the State Board of Health. As the results of hard work in Minnesota the relations have been so altered that now he is able to announce, for the first time, that the proportion existing between the medical profession and the general public is as 1 to 1,300.

The Committee in its report recommended that such legislation should be secured as would provide for a careful preliminary examination, a definitely prescribed course of study, an examination upon presentation of diplomas, and adequate power for the revocation of licenses.

In the discussion of the report DR. N. S. DAVIS entered an eloquent plea in support of the proposed measures.

DR. MILLARD said that a very carefully prepared law had been framed, and that it was hoped that the various States would enact similar legislation, so that the regulations for medical practice might be practically the same throughout the country.

DR. GIBON said that the most important consideration was the matter of preliminary education.

DR. SCAMMON, of Tennessee, agreed substantially with the views expressed by the others, but was in favor of having the State Board elected by the profession.

DR. ARMSTRONG suggested that Dr. Scammon misunderstood the matter, as the manner of constituting the Board was not set forth in the resolutions.

DR. STORER, of Newport, said that the whole matter had been a live question in Rhode Island for several years; that an irregular practitioner had been cleared of a charge of malpractice on the ground that a practitioner was only obliged to exercise a fair degree of skill and that the law did not require the physician to know very much. He was in favor of the proposed changes.

On motion the resolutions were adopted and committed to the general Association with the request that they be transmitted to the various States for their consideration.

DR. J. B. HAMILTON explained the disinfecting apparatus in use in New York, illustrating his remarks by means of a chart.

### THIRD DAY, JUNE 27.

DR. HARVEY, of New York, read a paper on *Sanitary Disposition of the Dead*. He said: This subject is one that has long received the attention of the Association, but it has made little advance among the masses. Could a picture of what is going on below the surface of the earth in our graveyards be seen in contrast with the life above it would be disgusting and horrible in the extreme. Dr. Gross said that it took from forty to sixty years for the dead body to decay. In Paris frightful epidemics have been traced to their source in the cemeteries. In Italy experiments made by inoculation with germs from air polluted by the emanations from the dead produced typhus in animals. Gravediggers have been known to die almost immediately upon entering vaults where dead bodies were kept. The facts of water pollution by this means are well known. Cremation is of course extremely obnoxious to some, but a method of disposing of the dead has been discovered which, while effectual in the reforms desired, does not offend the sensibilities of the most delicate. This is the method of dessication, whereby bodies laid away in elegant mausoleums can be exposed to the action of hot, dry air, with the effect of removing, in the course of three or four months, all the more volatile elements of the body. In this way all danger of epidemics from this source is removed. The method is not open to the objection made by jurists to cremation, viz.: that it destroys all evidence of crime.

Discussed by Drs. Formad, of Philadelphia; Carrol, of New York; and Harvey.

DR. MARCY, Chairman of the Committee on *The Coroner System in the United States*, then made a brief oral report of the work accomplished. He said that the Committee had accumulated material enough for a good-sized volume. The existing laws, he said, are very objectionable, both from a medical and legal standpoint; in Massachusetts, Rhode Island, and Connecticut, however, he was glad to report that material improvements have already been made.

DR. G. H. ROHÉ, of Baltimore read a paper entitled *The Necessity for Sanitary Supervision of Schools*. Dr. Rohé directed attention to the fact that nearsightedness increases in proportion to the grade of the schools, both in regard to frequency and degree of severity, the condition being much more frequent and serious in the higher schools. The causes are largely dependent upon the arrangement of the seats and light. Large clear type and good paper should be used in all text-books. The relations as regards pulmonary consumption and spinal deformity were also considered, five-sixths of the cases of the

latter disease having been shown to begin during school life. Nervous and digestive derangements received attention from the reader, who advocated the cultivation of more muscle and less brain. Contagious diseases have sometimes to be met by temporary suspension of schools. Vaccination regulations are not well carried out. Heating and ventilation require adequate supervision. To secure the proper regulation of these important considerations an expert officer should be appointed whose duty it should also be to examine plans for school buildings; to inspect all buildings in use from time to time from an hygienic standpoint, to look after the proper vaccination of the pupils, to guard against the spread of contagious diseases, to enforce the adoption of text-books of suitable type. Such an inspector should be required to visit every room at proper intervals of time, to test the pupils' eyes every year, and to make reports once a year to the School Board. For such work an excellent hygienist is needed. Dr. Rohé in his observations has found that School Boards are anxious to know just what their duties in these various directions really are.

Discussed by Drs. Schenck, of Kansas, and Lincoln, of Massachusetts.

Resolutions regarding the formation of a committee to inquire into the advisability of securing such legislation as Dr. Rohé had suggested were introduced by Dr. Lincoln.

The discussion was then resumed and entered into by Drs. Pinkham, of Massachusetts; Bell, of New York; and Gihon, U. S. N.

The resolutions were then adopted, and Drs. Lincoln, Rohé, Reed, and Pinkham were constituted a committee to take the matter in hand.

DR. CARROLL, read a paper on *Disposal of House Refuse*. He drew attention to the fact that the danger from excreta is chiefly after fermentation has taken place, and this danger is increased by the influence of certain diseases. Cess-pools and privy vaults are extremely dangerous to health. Disinfection of these by earth or charcoal is efficient, but impracticable in large cities. Such refuse may be rendered innocuous by spreading it on the ground in thin layers with free exposure to the air. House garbage, however, is the greatest bane we have to deal with. This should be burned, and much of it can be disposed of in the kitchen range.

DR. GIHON moved a vote of thanks to the reader of the paper, which was promptly carried.

DR. SWARTZ, of Rhode Island, read a paper on *The Control of Epidemic Diseases*. He believes that chemists, bacteriologists and veterinaries should be made assistants to the health authorities by which the means of controlling epidemics would be greatly strengthened. He described the spread of two epidemics in Rhode Island. In the first one he made bacteriological and other

examinations in various directions without finding the bacilli of typhoid fever, although the cases had been reported as of typhoid origin, but a water bacillus was found in the milk used by the sick, and was thence traced to its origin, in the water supply of the cattle. The pasturage was changed with the effect of checking the epidemic. He is of opinion that in this epidemic the poisoning may have been due to the formation of a ptomaine. The other epidemic referred to occurred in Providence, the origin was found in typhoid stools which had been thrown on the river bank.

Other papers were read by title.

#### SECOND DAY, JUNE 26.

[The discussions will be printed with the papers in the order in which they are published in THE JOURNAL.]

DR. J. B. LINDSEY, Chairman of the Section, delivered an Address on *Popular Progress in State Medicine*. (See page 73.)

DR. GEO. MINGES, of Dubuque, read an interesting paper on *Bacteriological Examination of Several Native Mineral Waters in the Bottled State*.

The author finds that the bacteriological examination of drinking-water has become more important than the chemical analysis. Water from pure springs is free from bacteria especially if it contains free carbonic acid. In bottled water there are often very many. These are derived chiefly from the corks and from unclean bottles. Sulphuretted hydrogen inhibits the development of bacteria to some extent. Aerated bottled water contains more bacteria than that which is not aerated. Bottles should be cleansed by boiling water or steam.

DR. CHAS. V. CHAPIN, of Providence, R. I., read a paper on *The Purification of Drinking-Water for Cities*.

Dr. Chapin discussed this subject in a very thorough manner, confining his remarks, however, mainly to the purification of water by filtration. He believes that domestic filters, with the exception of the very expensive Pasteur filter, are worse than useless. Sharp, fine sand is the best practical agent for use, and fresh sand is less useful than that which has been in use for some time, because after being in use for some time organic matter covers the particles of sand, and this serves to arrest the bacteria. Water has been filtered on a large scale, and in Berlin, London, and many of our own cities, water containing 11,000 microbes per ccm. before filtration has been found to contain only 179 after. The process of filtration on a large scale has been facilitated by the coagulation produced by the addition of a small amount of alum.

Discussed by Drs. Smart, U. S. A.; Mercer, of Syracuse; Minges, of Dubuque; Baker, of Lansing; Mercer and Chapin.

DR. N. S. DAVIS, of Chicago, presented the *Report of Standing Committee on Meteorological Conditions*.

As regards the Collective International Investigation of Disease he was obliged to say that the Committee had scored a failure, but in other lines of investigation he could say that he had accumulated a mass of valuable statistics. These were the results of observations obtained from the Signal Service, from a chemical daily examination of the atmospheric air, and from the reports of physicians as to the exact date of the beginning of attacks of acute diseases.

On motion the Section resolved to recommend that the Association continue the Committee, but that it be excused from the International Collective plan. It was also resolved to cooperate with the various State Boards of Health.

DR. A. L. BELL, of Brooklyn, read a paper on *Stamina*.

Dr. Bell stated that it was his object to reduce the importance of such expressions as susceptibility, heredity and predisposition. Health is something more than the mere freedom from disease. Immunity from disease is largely due to "stamina." People who live under conditions of life requiring little energy do not live to old age, and heredity is amenable to the same organic forces as feebleness of constitution in general. Offspring of poorly nourished parents are scarcely less liable to pulmonary consumption than the offspring of those affected with that disease.

The election of Section officers was then held. Dr. J. B. Hamilton, U. S. Marine-Hosp. Service, was elected Chairman, and Dr. F. S. Bascom, of Utah, Secretary.

DR. H. B. BAKER, of Michigan, read a valuable paper on *The Climatic Causation of Consumption*.

In a very extensive and elaborate consideration of this subject Dr. Baker laid down the following propositions: 1. Low moist ground tends to consumption. 2. Cold dry air has a similar tendency. 3. The bacillus is acknowledged as the proximate cause of the disease. In a somewhat elaborate argument, supported by a vast array of facts, the reader undertook to reconcile these apparently irreconcilable ideas. Dr. Baker illustrated his subject by a large number of tables with which his hearers were furnished. Not the least interesting of his statements was the one that whereas 73 per cent. of mankind are inoculated with tuberculosis, only 13 per cent. die of the disease.

Discussed by Drs. Flick; Lyster, of Michigan; Bell, of Brooklyn; N. S. Davis, of Chicago; Rives, of New York; Hibbard, of Indiana; and Minges, of Iowa.

DR. F. S. BASCOM, of Utah, read a paper on the *Climatological Characteristics of Salt Lake City*.

Dr. Bascom presented a very attractive picture

of the advantages offered by his city, it having proved itself to have the requisite qualities of dryness, equable temperature, moderate altitude, sunshine, and freedom from high winds and electric storms.

DR. BAKER criticised the author in that he had given only the *relative* and not absolute humidity, and had not supported his claims with tables of sickness and death.

### *Section on Ophthalmology.*

FIRST DAY, JUNE 25.

The meeting was called to order at 3 P.M., Dr. C. E. FROTHINGHAM, of Ann Arbor, in the Chair.

The Chairman read an excellent address, in which he emphasized very strongly the necessity of discussing freely many questions in ophthalmology about which there is an apparent agreement, but which, notwithstanding, are unsettled. Various of these subjects were mentioned, and his suggestions were eminently practical.

DR. ROBERT TILLEY, of Chicago, read a paper on *What can we do to induce the Government to make the Census of 1890 contribute efficiently to a clear conception of the causes of Blindness.* After stating that Dr. Magnus had in Germany succeeded in obtaining reliable reports on the causes of blindness, and having enumerated these causes, Dr. Tilley strenuously advised that the same system be adopted in this country, and for this purpose he presented the printed blanks used by Dr. Magnus. The main object of the paper was to have an effort made to ascertain the causes of blindness and then attack them more intelligently.

Considerable discussion followed this paper, in which Drs. Connor, Scott, Jackson and Thompson took part. Finally it was moved and carried that a committee be appointed by the Chair to request the General Assembly to authorize the Section on Ophthalmology, together with the American Ophthalmological Association, to confer with the Census Committee. Drs. X. E. Scott, Robert Tilley and J. Chisholm were appointed on this Committee.

DR. A. E. PRINCE, of Jacksonville, Ill., read a paper on *The Prevention of Pain and the Improvement of the Stump following Evisceration of the Eye.* Having failed in preventing pain in the stump in five cases of evisceration, Dr. P. was led to try carbolic acid, applied to the anterior portion of the stump, with very good results. He had used the glass ball (artificial vitreous), but was not satisfied, and has finally adopted the system of filling the empty shell with iodoform and packing it in with cotton, and then inserting sutures. He is well satisfied with this method. Dr. Prince also exhibited a book for keeping the record of patients in such a way that they can be easily found and tabulated.

DR. JACKSON stated that Dr. Williams, of Boston, was the first to record a case of evisceration. Dr. Williams was thereupon asked to speak on the subject. He stated that he preferred evisceration on account of its safety. That for the prevention of pain he used cold-water applications; and that he was pleased with the result.

The third paper was read by DR. W. H. WILLIAMS, of Boston, on *Advances in our knowledge of some Cerebral, Ocular and Intra-Orbital Lesions which facilitate the Diagnosis and Treatment of Important Diseases.*

In this paper a number of very interesting cases of ocular disturbance produced by brain and kidney disease, which showed how important a part a careful examination of the eye plays in making a careful diagnosis of these diseases, for in many of these cases internal disease was not suspected until the ophthalmoscope revealed its symptoms in the eye. Dr. W. also reported some very interesting cases of blindness following facial erysipelas.

Discussed by Drs. Chisolm, Knapp, Leartus Connor and Noyes.

DR. J. L. THOMPSON, of Indianapolis, then read a paper entitled *Some Cases of Inflammation and Atrophy of the Optic Nerve, with Special Reference to Etiology and Prognosis.* After reporting a number of interesting cases and commenting on the difficulty of making a prognosis, and in tracing the disease to its origin. He read the following conclusions as the result of his observation: 1. Progressive atrophy with no evidences of former inflammation gives bad prognosis. If one is affected the other remaining for several months unimpaired, prognosis favorable for this eye. 2. In atrophies following pernicious intermittent fever, improvement sometimes takes place when least expected. Inflammation of the optic nerve resulting from violent exercise, disturbances in menstruation, etc., occurring in plethoric persons admit of very favorable prognosis. Inflammations of the optic disc caused by brain tumors often improve so much that one is liable to doubt his diagnosis or to modify views as to prognosis, but death is the result, with few exceptions.

This paper was discussed together with that of Dr. Williams.

It being quite late it was moved and carried that the reading of papers be postponed until Wednesday at 3 P.M.

The Committee for Nomination of Officers for the next meeting was appointed. Drs. X. E. Scott, A. E. Prince and J. Chisolm were placed on this committee.

The meeting then adjourned.

SECOND DAY, JUNE 26.

The meeting was called to order at 3 P.M., DR. G. FROTHINGHAM in the Chair.

DR. E. J. GARDINER read a paper on the *Non-*

*Surgical Treatment of Strabismus Convergens.* After stating its advantages, and making manifest the dangers of hasty operative interference, he reported twenty-five cases in which the only treatment used was correction of ametropia and atropine, the orthoptic measures having been omitted experimentally. The correction was over 50 per cent. of all cases recorded.

Discussed by Drs. H. Knapp, P. D. Keyser, J. L. Thompson, R. Tilley, G. Frothingham, S. C. Ayres, J. Chisolm and Geo. Stevens.

DR. LEARTUS CONNER then read a paper on *Tobacco Amblyopia*, which proved to be very interesting, because a full history was given of two cases, where the trouble supervened in total abstinents, one a gardener, the other a clergyman. Both were typical cases, and both recovered by leaving off smoking and using strychnia. Dr. Conner stated that he had not been able to find a well authenticated case of alcohol amblyopia where tobacco could be excluded, and believes that tobacco causes the trouble. He then propounded a number of questions about which different opinions are entertained by ophthalmologists, one of them the etiology of central scotoma.

Discussed by Drs. H. Knapp, Myles Standish, Noyes, P. D. Keyser, J. Chisolm, Blitz, and E. J. Gardiner.

DR. S. C. AYRES read a very instructive paper on *Tumors of the Optic Nerve*. After reviewing the literature on the subject he proceeded to give a history of two cases, with microscopical examination of the tumors. The first case was a little boy who presented all the characteristic symptoms of intraorbital tumor. It was removed and proved to be a myxosarcoma, which began in the connective tissue of the optic nerve sheath. The lad remains well. The second patient was a young lady, with a large-sized myxosarcoma of the optic nerve sheath. This young lady died six months after operation from typhoid fever. Dr. Ayres thinks that the majority of these tumors are of the myxosarcomatous variety, that they spring from the open nerve sheath, and that the prognosis is favorable.

DR. P. KEYSER reported two cases of this disease operated upon many years ago, who are still alive and well.

DR. J. A. LIPPINCOTT operated on a case four years ago. The lady is doing very well.

DR. THOMPSON stated that he saw Dr. Williams, of Boston, operate on one, and Dr. Hamilton, of Ohio, upon another, with good results.

DR. JULIAN CHISOLM then read a paper on *The needless and annoying Restraints after Eye Operations*. He stated that confinement in bed was unnecessary even in iridectomies and cataract operations. The dark room he had discarded, using for his cataract patients a moderately darkened room—a good daylight to make examinations of the operated eye. Antiseptics he thought

unnecessary if thorough cleanliness was enforced. For the eye bandage he has substituted the isinglass entirely, and obtains excellent results by following the more easy method. He does not restrict the diet, allowing the patients to indulge in their regular habits. The securing of the hands after cataract operations he considered entirely unnecessary.

The next paper being on the subject of cataract, the discussion was deferred until after it was read. Its title, *Glaucoma Fulminans after Operations*. The writer, DR. P. D. KEYSER, reported two cases in which, after a perfectly smooth and uncomplicated operation for extraction was performed, at the end of six days in one case, on the third day in the other, sudden and severe pain was felt, and when the eye was examined, the characteristic picture of glaucoma fulminans was discovered. The hæmorrhage in both cases was copious. In the first case the operation had to be postponed for a few days, and the result was a loss of sight; in the other case the iridectomy was immediately performed and good vision was restored. Dr. Keyser was at a loss to explain the cause. He recommended the opening of the posterior capsule.

Discussed by Drs. Ayres, Tilley, Jackson and Knapp.

The papers of the following gentlemen were called but, the writers being absent, were passed: Drs. Eugene Smith, of Detroit; Le Roy Dibble, of Kansas City; J. H. Thompson, of Kansas City; Dudley Reynolds, of Louisville, Ky.

On motion the hour of meeting for the next meeting was made 2:30 P.M.

The meeting then adjourned.

### THIRD DAY, JUNE 27.

The meeting was called to order by the Chairman, Dr. Geo. Frothingham, at 3 P.M.

The Chairman announced that Dr. S. C. Ayers, of Cincinnati, had been elected Chairman, and Dr. E. J. Gardiner, Secretary, of the Section for the ensuing year and that the next meeting of the Association would be held at Nashville, Tenn.

DR. J. E. COLBURN, of Chicago, then reported *Two Cases of Complications Arising During Cataract Operation*.

In the first case, after making a perfectly smooth section of the cornea, and previous to making the iridectomy, the whole contents of the eye escaped. A grayish substance was afterwards discovered in the eye; on the following day a large hæmorrhage filled the eye.

The second patient was a man in good health. Mature cataract, central perception was very poor, peripheral perception good. While making incision noticed bead of vitreous, but succeeded in making iridectomy, and removing the lens with no further complication. While patient was resting quietly after operation he suddenly cried out

with pain. Examination revealed a condition similar to that of the first case. The eye was subsequently enucleated. A calcified ring was discovered around the optic nerve.

DR. KNAPP was then requested to report on his experience in opening the capsule while making the corneal section. Dr. K. complied with the request by reading a paper which he had prepared for the *Archives of Ophthalmology*. He stated that he had tried to open the capsule while making the corneal section in sixty-four cases. In sixty-one he had succeeded. In three he found difficulty. The first case in which difficulty was experienced was one of hypermature cataract. Dipped point of knife into capsule, but it did not cut and the lens would not come out. Made peripheral capsulotomy and extracted lens without difficulty. Healing without reaction, vision  $\frac{2}{40}$ . No secondary operation was made. 2. Point entered capsule but could not cut through, it being very tough. Had to draw the knife back, the iris fell before the knife and was cut. Iridectomy was performed, and some vitreous escaped. The wound healed kindly. Vision  $\frac{2}{40}$ . 3. Ordinary cataract, anterior chamber very shallow. Point of knife punctured iris, had to draw the knife back and cut iris. Healing took place without complication. Vision good.

The advantages of the operation are that it simplifies the operation by merging two steps into one, and that one instrument is dispensed with, thus diminishing the danger of infection. If the simple operation is performed the knife is the only instrument that enters the anterior chamber. The disadvantages are: That even under the most favorable circumstances the operation is difficult, by reason of the change in the direction of the knife. When the anterior chamber is shallow, the pupil narrow, or the cataract hypermature, the difficulties are much increased. Dr. Knapp thinks there is no cogent reason for the operation.

Then followed a lengthy discussion on many details of extraction of cataract and secondary division of the capsule, followed mostly in questions addressed to Dr. Knapp, which he answered. Our space does not permit us to give a full report of all these remarks. The principle questions were: Whether Dr. Knapp would perform secondary operation if the patient could read? Answer—Yes; because we should strive for the very best results obtainable. How soon after the first operation did he perform the secondary division? Answer—From three to six weeks, preferred a little more time to elapse. Sometimes it could be done after the thirteenth day. Was the operation performed by ordinary daylight? Answer—No; always by focal illumination, which is the only way to thoroughly illuminate the field and discover the best place for the incision.

A paper on *The Ametropic and their Relation*

to *Insufficiencies of the Recti muscles*, by Dr. Wright, of Columbus, O., and also one entitled, *Embolus of the Inferior Branch of the Retinal Artery Visible with the Ophthalmoscope; Disappearance of Embolus and Recovery of the Greater Part of the Field Under Massage and Nitrate of Amyl*, by Dr. H. Gifford, of Omaha, Neb., were read by title.

DR. J. E. COLBURN requested that his paper on *Insufficiencies of the Recti Muscles, with Report of Cases*, be read by title, because it was on the same subject as that of Dr. Stevens, of New York, and that he would report one of his cases in the discussion of Dr. Stevens' paper. Dr. Colburn's request was granted.

DR. G. T. STEVENS, of New York, then read a paper entitled, *Respecting the Determination of the Deviations in Strabismus and their Treatment*.

Several cases were reported illustrating the important part which the vertical deviations play in the production of strabismus, and also showing the importance of detecting these deviations. He then concluded by calling attention to the following principles here briefly stated and abridged:

Results of examination for strabismus should be expressed in angles and not in linear measurements. To this end diplopia must be recognized and the double images carefully located. In cases of moderate strabismus this can be accomplished, with patient and intelligent effort. Extreme cases should be converted into moderate cases for better observations. The relative position of the double images is sometimes contrary to well-known laws, and unless the surgeon is on his guard, may be misleading. These exceptional positions of the images should lead us to the conclusion that the case is probably one of hyperopia. The unequal tension of the two pair of superior and inferior recti is often responsible for an apparent converging or diverging strabismus. The standard operation for strabismus by reason of its disabling effect upon the severed muscle, is an obstacle to a perfect result.

Graduated tenotomies, in which no tendon is disabled from performing the full required rotation of the eye, combined with tendon resection of the opposing muscle, operations if need be to be made on several muscles should supercede the severing of the tendon completely.

DR. J. E. COLBURN reported the case of a brawny Irishman who had an apparent divergent strabismus due to hyperphoria. He operated and the divergent entirely disappeared.

Discussed by Drs. Jackson, Savage, Tilley, Connor, and Gardiner.

DR. A. BLITZ, of Indianapolis, Ind., read a carefully prepared paper reporting *A Typical Case of Ocular Irritation Caused by Chronic Rhinitis Relieved by Treatment of the Nasal Trouble*. In the discussion which followed, several gentlemen spoke, reporting interesting cases of this character.

The work of the Section having been finished, DR. FROTHINGHAM thanked the gentlemen who had so efficiently helped to make the meeting successful, both by the careful preparation of papers and by participation in the instructive discussions which in every case followed the reading of the papers.

On motion, a vote of thanks was tendered to the President and Secretary of the Section, and to the reporter of THE JOURNAL.

A vote of thanks was tendered to the Committee of Arrangements for their kind attentions in procuring such excellent rooms for the meetings of the Section, and the thanks of the Section of Ophthalmology was tendered to the Casino Club for allowing the use of their beautiful rooms for this purpose.

The meeting then adjourned.

## FOREIGN CORRESPONDENCE.

### LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

*M. M. Germain Sée and Laborde on the Utility of the Exclusive Administration of Alkaloids extracted from Plants—Dr. Bouilly defends the Use of Pessaries—Dr. Mossé on the Re-plantation of Bones removed by the Trephine—An anonymous writer in "The Scalpel" on the Hemostatic Action of Cocaine—Dr. Deyon on the Action of Bromide of Potassium.*

With reference to the debate that lately took place at the Academy of Medicine, M. M. Germain Sée and Laborde maintained the utility of the exclusive administration of alkaloids extracted from plants. The immediate principle, they say, is always *one*, identical in itself, invariable in its proper constitution, as in its fundamental, physiological and medicamentous action, the total matter which contains it is complex, variable in its composition as it is in its effects. Apropos of this subject, a writer in the *Gazette Hebdomadaire* remarks that while it may be admitted that the preparations taken from plants may contain divers alkaloids, it is precisely because the matter extracted from a plant is variable in its composition that its effects differ from the action exercised by a single alkaloid. As successively stated by M. M. C. Paul, Trasbot and Gariel, chemical analysis has not isolated, and never will isolate all the active principles which a plant contains. The latter contains not only crystallizable substances, but also soluble substances, and if it becomes possible to isolate all, it will still be difficult to combine and associate them to produce the therapeutic effect obtained in employing the plant itself. It may therefore be concluded that digitalis is an excellent medicament and which

produces effects very different from those which are produced by digitaline, that the extract or the tincture of aconite should be preferred to aconitine, that, in children it would be very dangerous to substitute emetine for ipecacuanha, in a word, the medical practitioner should know how to formulate, that is to say, in combining and associating the divers medicaments of which a long experience has demonstrated the efficacy. In illustration of the inconveniences of alkaloids, I may here cite the researches of Dr. Alfonso Montefusco, published in the *Giornale di Clinica*, in which the author states that scillitine has no diuretic property. It determines a diminution in the force and in the frequency of cardiac contractions as well as a lowering of the sanguineous pressure. Injections of this substance diminish the frequency and the force of the respiration. It has no action whatever on sensibility and on motility.

At the Société de Chirurgie Dr. Bouilly defends the use of pessaries and tried to prove that they are useful and that they are not dangerous. He would not, of course, defend the employment of those enormous pessaries that were formerly in use, but he would willingly adopt instruments, whether malleable or not, which, are made to measure, and which adapt themselves to the parts to which they are applied, such for instance the pessaries of Hodge and of Smith. Dr. Bouilly thinks that they are clearly useful in simple, mobile, retro-deviations, and that it would be dangerous not to maintain the uterus in position. Between doing nothing on the one hand, or practicing Alexander's operation on the other, which does not often produce satisfactory results, there is a treatment to institute, and that is that of the application of a pessary. Dr. Bouilly had already collected 84 cases of retro-deviation in which he employed this instrument and which always proved satisfactory. But to apply the pessary reduction must first be effected, either by the genu-pectoral or knee-and-chest position, or by the method of Schultze. In these conditions an instrument of good dimensions reestablishes the cul-de-sac of Douglas, the portion of intestine that was displaced will resume its normal position, and in directing the attention of the patient to the necessity of not allowing the bladder to get full, of avoiding shocks, pregnancy may take place, or the maintenance of the uterus in proper position may be obtained in eight or nine months of treatment. The danger is *nil* when the pessary is well applied, and accidents may occur only in cases where the instrument is too large, ill-chosen and badly applied to a womb imperfectly reduced. Only once did M. Bouilly see an ulceration in the posterior cul-de-sac, and it was healed up in a few days. It is, of course, understood that the posterior adhesions are a contraindication. M. Pozzi supports the opinion of M. Bouilly. M. Terrier

thinks that this question might be discussed for a long time, it is to experience that the demonstration of the fact must be left. As far as he is concerned, without having applied as many pes-saries as M. Bonilly, he thinks that this instrument is without any action, unless it acts by auto-suggestion analogous to a case he had reported at a previous meeting.

Dr. Mossé, of Montpellier, has published a note on the re-plantation, practiced with success, of fragments of bones removed by the trephine. These operations had been performed on rabbits, dogs and monkeys. The experiments consisted: 1. In re-plantations, on the same animal, of a rundle of the skull removed by trephining. 2. In the transplantation on an animal, of the same species, of a rundle of bone removed from the first subject. 3. In the transplantation on an animal of a different species. In all these experiments the crown of the trephine was applied to the bone, the periosteum of which was scraped and turned over with the skin, without any precaution being taken to preserve the periosteum itself. After having replaced the bony rundle in position, the soft parts were simply reunited above the rundle by points of suture. After a certain time the animals were sacrificed, and it was found that in the greater part the osseous rundles were soldered to the neighboring tissue. These experiments had been practiced on man by Ewen, Barrel and Horsley. The results obtained by these experimenters would authorize one to think that a rundle trephined is susceptible of being grafted in the place it occupied before its removal.

An anonymous writer in the *Scalpel* on the hæmostatic action of cocaine, remarked that, for the last three years he had recourse to the subcutaneous injections of the hydrochlorate of cocaine to produce local anæsthesia, that after these injections there was no hæmorrhage, or at least the flow of blood was less than when he did not employ cocaine. From this fact the idea struck him that it would be a useful means against excessive hæmorrhages, which are sometimes difficult and long to arrest. With the view of correcting the flow of blood, the author tried the direct application to the bleeding surface, of pads of charpie imbibed in the following solution: Hydrochlorate of cocaine, 1 gram, alcohol, 5 drops, laurel-cherry water, 5 grams. He sometimes applied the powder of cocaine to the wound, at others he employed a subcutaneous injection of the same substance, in the neighborhood of the seat of hæmorrhage. The first mode of application succeeded in rapidly arresting a severe attack of epistaxis. Suppositories containing from 15 to 20 centigrams of cocaine have always succeeded in arresting persistent oozing of blood. Commenting on this note, Dr. Fano, in the *Journal d'Oculistique*, observed that this latter dose of co-

caine is not without danger. It is well known with what facility and rapidity is accomplished the function of absorption in the rectum.

Dr. Doyon, writing on the accumulation of the bromide of potassium in certain organs, states that this salt preferably accumulates in the central nervous system, which is not surprising, as it exercises its physiological action particularly on the nervous centres. It is found also in large proportions in the liver.

A. B.

## LETTER FROM SAO PAULO, BRAZIL.

(FROM AN OCCASIONAL CORRESPONDENT.)

*Yellow Fever—Unprecedented Severity of Epidemic of 1889—Can true Yellow Fever pass the Coast Range and become Epidemic in the Uplands of the Interior?—Influence of bad Sanitary Conditions—Does Freire's Inoculation of the Attenuated Microbe Protect?—Sudden Deaths—Beriberi.*

It is quite certain that since the epidemic which devastated Memphis in 1878, nothing has happened in the history of yellow fever so severe as that which has decimated Santos and Camfinas this year.

The epidemic in Rio de Janeiro presents few new features, and the frequency with which the city is visited by yellow fever, its commercial importance and rapid and frequent communication between it and the States, place the matter within easy reach of your readers. Not so with Santos and Camfinas.

Santos is, after Rio, the most important of the coffee ports. A city of about 20,000 souls, situated just within the tropics, it is almost entirely surrounded by water; in fact, at high tide it is completely surrounded by the sea. The business part of the city is but little above the tides and is cut off from the sea breeze by Mt. Serrate, a high point within the city limits. Some years ago drains were constructed under the streets to carry off the rain-water, but there is no system of sewers. During the last few years permission has been granted to householders to connect their privies and house service with these loosely built mains. No precautions whatever have been taken in the way of tide flaps on the lateral pipes, so that the incoming tide, which flushes the drains of the lower part of the city, carries back the accumulated filth, forcing poisonous gases back into the tide drains. The soil has become thoroughly impregnated with fecal matter, as the bricks at the bottom of the drains are laid without mortar. The city is supplied with drinking-water from the neighboring mountains, of excellent quality, but in quantity inadequate to the demands of the city. The present season has been noted for the almost total absence of rains, the heat has been intense and continued, for weeks and weeks, often reaching 36°C. in the shade and 54° in the sun. Under

these conditions it is not strange that yellow fever should make its appearance, particularly as the streets and tenements of the city have been full of the poorest class of Italian immigrants for months.

On the 14th of January a man who had not been out of the city was seized with yellow fever and died. From this case and date the disease spread over the city. Several cases about this time were landed from foreign steamers, and were taken to the hospital and died, but it is true that the first case *was not imported and had not been in contact with foreign shipping*. Early in February the inhabitants began to abandon the city, so that during the height of the epidemic not more than 10,000 or 12,000 remained. The deaths in the city, so far as can be ascertained, from January 14 to date, have been 1,238. This does not include those who died outside of the city who had been exposed before leaving.

It is difficult to estimate the proportion of deaths to the number attacked. At one time at least one-third of the whole population was prostrated with some kind of fever. As nearly as I could judge by visiting the hospitals and accompanying some of the most prominent physicians in their private practice during the height of the epidemic, about 40 per cent. of all the cases were different types of malarial fever.

The most striking feature of the epidemic both in Santos and Rio was the great frequency of sudden deaths, falling down in the street, becoming unconscious and dying in from two to eight hours. The native doctors call these cases of "*acesso pernicioso*"—pernicious attacks.

In the confusion and panic incident to an epidemic like the present one it is almost impossible to get at the real facts. The exact character of these cases "*fulminantes*" has not been determined; whatever it may be it is clear that it is *not* sunstroke, as these cases are strictly confined to the places where yellow fever is epidemic.

In the early days of the epidemic it was difficult to organize the medical or sanitary service. Temporary hospitals were opened, but, with the overworked doctors and entire absence of nurses, they were little more than convenient places to die in. In the public hospitals the death-rate was something fearful, probably 80 or 90 per cent.

So far as treatment was concerned it was mostly palliative. The physicians are divided into three classes: those who gave quinine in all cases, those who discriminated carefully between yellow and malarial fever and who never gave quinine in the former, and those who treated symptoms only. The treatment employed in the Garcia Hospital, at Havana, was tried with fair success by Drs. Miranda de Azevedo and Henschel. The influence of order and perfect organization under good conditions was strongly accentuated in the Portuguese Hospital; which, by the way, is a model hospital

under the very best of direction. Here Dr. Furtado lost only about 10 per cent. of the yellow fever cases. This physician does not use quinine in any stage, but after the preliminary treatment relies on alkalies and salicylate of soda, followed by perchloride of iron and iodine.

The disease at Santos and Rio has nothing particularly new about it, presenting about the same features as are found in the sweeping epidemics of our own country. But the outbreak at Camfinas is altogether new.

#### CAMFINAS.

This city is situated on the first plateau of Brazil, 2,250 feet above sea level and 160 kilometres from the coast in a straight line. It is somewhat lower than the range of mountains that separate it from the coast. The city is in a sort of basin surrounded on three sides by low hills. The population is estimated at 20,000. The houses are built without any attention to requirements of health, and in the poorer quarters crowded with Italian emigrants, six, seven and eight families often occupying the same house. There is no attempt at drainage, each house having its own privy vault, often only a shallow excavation in the back yard in close neighborhood to the well. The cemetery is situated on the brow of the hill just above the town, and in the soft, porous earth it is fair to suppose that the wells get the full benefit of it. The heat in Camfinas is quite as intense as in Santos, the absence of rain more sensible because of the absence of the ocean or any other body of water. Under the old theory that yellow fever is a coast disease Camfinas would be safe from its ravages—but in spite of all theories it is true that it has this year been swept by the most destructive epidemic of yellow fever of which we have any account during the last half century.

On the 9th of February a German woman arrived in Camfinas from Santos with yellow fever and died in a Swiss bakery boarding-house. Within fifteen days the persons who slept on the mattress upon which the woman had died were taken sick and died also. The family nearly all died, and many of the customers of the bake-shop. About the same date a child was taken ill with what was supposed to be a bad type of bilious fever, in a house in which ten months before two persons had died of yellow fever contracted in Rio. The child died, and a competent physician pronounced it a case of genuine yellow fever. It is true, at all events, that other members of the family were taken down and died. From these two points the disease spread in widening circles until new foci were established in different parts of the city, spreading in time to every corner of the place. Violent discussions arose among the physicians as to the real character of the disease—some classified it as typhus, others as the black plague, others as the ictero-hæmor-

rhagic fever of the East. In the early days of the epidemic the clinical features of the disease were quite different from those of the fever raging in Santos. The temperature curves more abrupt, complete jaundice supervening on the second day, the thermometric record showing distinct intermissions, frequent cases of new invasion after entering upon a free convalescence, apthous sores in the mouth, rapid pulse, violent delirium, etc.—still showing many of the characters of yellow fever: the suddenness of the onset, the lumbar pains, the flushed face, injected eyes, and redness of upper thorax, tendency to hæmorrhage. Here and there, however, a clear and almost typical case of yellow fever was found. Very soon the large majority of the cases became unmistakably yellow fever. *Pari passu* with the development of the epidemic the ordinary malarial fevers began to assume a grave character, so that I would venture to say that 30 per cent. of the cases pronounced yellow fever were grave cases of remittent fever. I saw two such cases myself, both of which recovered, but one of which was attacked by genuine yellow fever afterwards. It was noticed that however severe an attack of either type of fever was, it conferred no immunity from the other.

The flourishing city was almost entirely abandoned; business was suspended and the inhabitant, including many of the physicians, fled for their lives, until not more than 3,000 remained, and neither medical advice, medicine, nor food could be had in the city. People who were recovering from the fever actually died of starvation. It seemed like one of the cities described in the times of plague in the middle ages. Soon, however, São Paulo went to the rescue. The provincial and the general government sent relief committees with supplies of food, medicines and nurses, and a systematic course of disinfection was instituted under Dr. Araujo Goes, who had been entrusted with the same work by the general government in Santos, aided by a corps of volunteer medical students from Rio. The epidemic reached its *auge* in April. During this month there were 893 deaths out of a population of not more than 3,000. The death-rate among the poorer classes was something frightful. I saw in one of the small tenements seven persons sick on three beds, in a room without a window, all Italians recently arrived.

#### BELEM DO DESCALVADO.

At this point, 350 kilometres from the coast, and 2,200 feet above the sea level, has up to date lost seventeen citizens from yellow fever, starting from a case which came from Camfinas. These cases are pronounced genuine yellow fever by physicians who are well acquainted with the disease; characterized by black vomit, jaundice, anuria and death. This city has the same un-

sanitary privies and wells in close contiguity and has been visited by the same heat and drouth. Its mean temperature in ordinary years being 20° centigrade. It has a mean during March and April of 30.5° centigrade.

#### RIO CLARO.

This city is 240 kilometres from the coast, and 614 metres above sea level. It has a population of 7,000, and is barely free from malarial fever, and has no system of sewers, but relies upon private sanitation; as usual, wells and privies are near neighbors. Yellow fever was brought in by the refugees from Camfinas and spread to the inhabitants. There have been twenty-three fatal cases among people who have not been out of town.

#### LIMEIRA.

Two hundred kilometres from the coast, 542 metres above sea levels, having last year a mean of 20.06° during March and April. This year an average temperature of 30° (centigrade) during the same period without rain. Fever was imported from Camfinas and spread to the inhabitants. Sanitary arrangements wretched as usual.

Now, while no one thinks that bad water, filthy privies, or bad drains, create or spread yellow fever, as numerous striking cases might be cited to prove that the disease was in the air, and carried by the air or by some solid substance, such as clothing, etc., still the conditions created by these bad sanitary elements contribute in some way to its getting a foothold, *as under the same climatic influences* the same conditions of heat and *absence* of moisture at the same altitude the disease has not obtained a foothold whenever and wherever the sanitary conditions were good.

This city of São Paulo, being only 40 miles from Santos, and receiving nearly half of its population as refugees, many of them arriving with yellow fever and dying here, having besides 12,000 Italian emigrants, recently arrived in Santos, and brought here after exposure to yellow fever, and many of these with the disease already developed, crowded into close quarters, has not had a single case of yellow fever that was not brought here from Rio or Santos.

Why this immunity? You must pass through São Paulo to get to Camfinas. Why should this disease pass São Paulo with a population of 50,000, and make its headquarters in Camfinas and the cities beyond? It is because these cities are clean, well drained and well supplied with pure water, and, in the case of São Paulo, well paved with clean granite.

There are numerous other points in the neighborhood of Rio that have been attacked by yellow fever, but while above the mountains they are in direct communication with an infected sea port by a water course. Such infections are not rare in the history of yellow fever epidemics,

but Camfinas, Limeira, Rio Claro, and Belem do Descalvado are out of the yellow fever range and form a new chapter in the history of the disease.

Dr. Domingos Freire came to Camfinas personally to superintend the inoculation of the people with his attenuated virus of yellow fever. Being obliged to return to Rio by the duties of his position, he left Dr. Angelo Simões in charge of the service. Up to the 7th inst., according to letter published, he had inoculated 630 persons, of whom only three had been attacked, and then in a mild form. The names and residences of these persons are recorded in the city offices, and are open for inspection and study.

In Santos, Dr. Barrata, a colleague and fellow professor of Dr. Freire, inoculated several hundred, chiefly among the foreign element, before the worst of the epidemic, and I am informed by reliable physicians, residents in Santos, that only a very insignificant number of those inoculated by Dr. Freire's method had yellow fever. These are significant facts in centres where, to escape an attack of the disease is the rare exception, and to have it, the rule.

Whatever may be said of the merits of Dr. Freire's attenuations from a scientific standpoint, these facts have a commercial significance not to be ignored. Whether he has found the microbe of yellow fever or not, or whether the fluid he injects contains the attenuated microbe or not, if it prevents yellow fever, or even if a large percentage of those inoculated escape in times of such sweeping epidemics as that of 1889, it deserves to be carefully investigated. Dr. Freire courts investigation. He, at least, has what is not always to be found among scientists, the courage of his convictions.

He seeks out the disease during dangerous epidemics, and in the face of his most determined opponent (Dr. Araujo Goes, who was sent by the government to Santos and Camfinas) makes the test fearlessly.

It is to be regretted that the gentleman who was sent out here by our government to investigate Dr. Freire and his method, could not have selected this season of the year for his studies, when yellow fever can always be found, and Dr. Freire is always at home.

So far as we can see in the scientific journals of the world that reach this distant point, Dr. Freire is on the top with his germ.

A disease which is rapidly coming into prominence now that the yellow fever excitement is subsiding, is beriberi, which, if it keeps on at the present rate, will before the year closes have a larger death roll than yellow fever. It is now almost epidemic in the prisons of the large coast cities, and also among the seamen of the marine.

S. Paulo, May 28, 1889.

## NECROLOGY.

### Henry F. Crain, M.D.

Henry F. Crain, M.D., a native of Walpole, N. H., was born September 22, 1810, the eldest son of Dr. Eleazer and Sarah Crain. At the age of 5 years his parents left Walpole and settled in the flourishing village of Springfield, Vermont, where he passed the greater part of his life. His father, a noted physician, pursued the study and practice of medicine and surgery during the remainder of his life, his death occurring in his 60th year.

H. F. Crain, after being well advanced in the common schools, completed the study of letters in the Springfield and Chester academies. Having decided to make the study of medicine and surgery his life work, he, under the able tutelage of his father and Dr. Amos Twitchell, of Keene, N. H., entered Dartmouth Medical College, attended the usual course of lectures, and was prosector to the professor of anatomy. He graduated, and commenced practice with his father in 1837. In 1838 he went to central Pennsylvania, where he practiced four years.

Having paid especial attention to gynecology, and believing that some mechanical design would be beneficial in the treatment of many cases of female complaints, he, in company with his father, invented the then famous spino-abdominal supporter, and for seven years manufactured and sold them to physicians and druggists; traveling in the eastern, middle and many of the western and southern states.

In 1849 he returned to Springfield, resumed the practice of medicine, and continued in active practice till 1882, when he removed to Rutland, Vermont, where in company with his son, Dr. M. R. Crain, by his ripe age, long experience, professional bearing, ready speech and affability of manners, he soon gained the confidence of a large and influential class of patrons, among whom he was appreciated to an extent seldom gained in so short a time.

He rarely neglected the wants of the sick, and was ever ready to alleviate the sufferings of his patients. Carefully investigating and diagnosing disease, he was prompt in the use of remedial agents.

He died March 16, 1888, after a protracted sickness, of eczema, complicated with disease of the heart. At the time of his death he was a member of the American Medical Association, Vermont State Medical Society, Rutland County Medical and Surgical Society, Rutland Medical Club and Connecticut River Medical Society.

In the death of Dr. H. F. Crain, the profession sustains a loss not easily repaired, the loss of one, who, during his long professional life, held strictly to the high dignity of the profession as taught and practiced in our regular schools and

colleges, never wavering from the true principle of medical ethics, discarding quackery, whether within or out of the profession. He was a critical observer of men and measures, of strong convictions, studious in keeping pace with the improvements in remedies or mechanical inventions for the better treatment of disease, testing every new element, giving rational reasons for approval or rejection. He had in his library books for reference from the most approved authors, foreign as well as American, of which he evinced a thorough knowledge, duly appreciating the great responsibility resting upon the profession which he so long and faithfully honored.

S. H. G.

## MISCELLANY.

**NEW YORK STATE MEDICAL ASSOCIATION.**—The seventh special meeting of the Fifth District Branch of the New York State Medical Association will be held in Port Jervis, Orange Co., N. Y., on Tuesday, Aug. 27, 1889. For those who are willing to spare the time after the meeting, a beautiful and interesting carriage drive of seven miles along the Delaware river to Milford, Penna., is promised. All are urged to make an effort to attend this meeting as the following Committee of Arrangements are making every preparation to insure an interesting meeting, both scientifically and socially:

Drs. J. H. Hunt, of Orange Co., Chairman; W. B. Eager, of Orange Co.; M. C. Connor, of Orange Co.; T. W. Bennett, of Sullivan Co.; W. H. DeKay, of Sullivan Co.; J. A. Munson, of Sullivan Co.

W. T. Lusk, M.D., President.

E. H. Squibb, M.D., Secretary.

P. O. Box 94, Brooklyn, N. Y.

**HEALTH IN MICHIGAN, JUNE, 1889.**—For the month of June, 1889, compared with the preceding month, the reports indicate that pneumonia, tonsillitis and influenza, decreased in prevalence.

Compared with the preceding month, the temperature in the month of June, 1889, was higher, the absolute and relative humidity and the day and night ozone were more.

Compared with the average for the month of June in the three years, 1886-88, inflammation of kidneys was more prevalent, and cholera morbus, measles, and inflammation of bowels were less prevalent in June, 1889.

For the month of June, 1889, compared with the average of corresponding months in the three years 1886-88, the temperature was lower, the absolute humidity was about the same, the relative humidity was more, and the day and night ozone much more.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of June, 1889, at 23 places, scarlet fever at 37 places, typhoid fever at 16 places, and measles at 19 places.

Reports from all sources show diphtheria reported at 1 place more, scarlet fever at 11 places less, typhoid fever at 6 places more, measles at 4 places less, than in the preceding month.

## *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from July 13, 1889, to July 19, 1889.*

Capt. Louis Brechemin, Asst. Surgeon U. S. A., ordered to Illinois National Guards, near Springfield, Ill., during remaining portion of encampment. Par. 1, S. O. 159, A. G. O., July 12, 1889.

Lieut. R. R. Ball, Asst. Surgeon U. S. Army, is granted leave of absence for fifteen days. Par. 3, S. O. 87, Dept. of the Missouri, July 9, 1889.

By direction of the Secretary of War, the extension of leave of absence on surgeon's certificate of disability granted Capt. H. G. Bunton, Asst. Surgeon, in S. O. 22, January 26, 1889, from this office, is further extended two months on account of sickness. Par. 1, S. O. 162, A. G. O., July 16, 1889.

F. J. Ives, Asst. Surgeon U. S. Army, now at Ft. Lyon, Cal., will proceed to camp near Oklahoma City, I. T., and report to the commanding officer for duty, relieving Capt. W. C. Gorgas, Asst. Surgeon, who, when so relieved, is authorized to avail himself of the leave of absence granted him in par. 2, S. O. 84, c. s., Dept. of the Missouri. Par. 1, S. O. 87, Dept. of the Missouri, July 9, 1889.

## *Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Five Weeks Ending July 13, 1889.*

Surgeon C. S. D. Fessenden, to proceed to Cairo, Ill., on special duty. July 8, 1889.

Surgeon W. H. Long, granted leave of absence for twenty-eight days. June 18, 1889.

Surgeon H. W. Austin, to proceed to Cairo, Ill., on special duty. July 8, 1889.

Surgeon Fairfax Irwin, granted leave of absence for ten days. July 6, 1889.

P. A. Surgeon F. W. Mead, granted leave of absence for thirty days. June 24, 1889.

Asst. Surgeon G. M. Magruder, relieved from duty at Baltimore, Md.; to report to the Supervising Surgeon-General for duty as acting Chief Clerk and attending surgeon. July 10, 1889.

Asst. Surgeon H. T. Goodwin, granted leave of absence for thirty days. July 8, 1889.

## ADDRESSES.

### ADDRESS OF WELCOME.

*Read at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June, 1889.*

BY HENRY E. TURNER, M.D.,  
OF NEWPORT, R. I.

*Mr. President and Gentlemen of the American Medical Association:*

The honor of presenting to you, gentlemen, an Address of Welcome on this highly interesting occasion, on the part of the local faculty of Newport, is one which I duly appreciate, as a flattering mark of confidence on the part of my associates, and as an agreeable form of introduction to yourselves, to whom I am very largely unknown, having never, though often delegated by the Rhode Island Medical Society, had the satisfaction of attending a Session of the National Association, because, generally, of the great distances of the meetings from my place of residence.

Newport, as a resort for health or pleasure, is more or less familiar to you all, but its pretensions as a centre of wealth, and taste and culture, in days long past, and especially of medical interest, are not as familiar to your minds, as to those of the residents of this ancient and formerly metropolitan borough; a few remarks of an historical character, have therefore seemed to me appropriate to the occasion.

During the greater part of the eighteenth century, Newport was the theatre of a very extensive and lucrative foreign trade, which came to a conclusion at the Revolution by reason of its occupation by British forces for a long period, and the consequent interruption to trade, and removal of a large proportion of its population, and the absolute loss and waste of much of its capital, and the diversion of a large part of the balance to other fields of industry; so that at the conclusion of the war it presented a scene of desolation, dilapidated wharves and store-houses, neglected buildings, streets and dwellings and general decay, and an idle and poverty-stricken population in place of one characterized as formerly by all the marks of thrift and industry, and only feeble remnants of the elegance and style formerly exhibited, and in which, in the heyday of its prosperity, it had been preëminent.

One result of the wealth and hospitality, and high cultivation of the better classes of Newport society, was the inducement presented by constant familiar association with European capitals, to men of culture and refinement, to take up a temporary or permanent residence in Newport, whose natural attractions were then as now, highly appreciated; and we find, accordingly, a galaxy of names of medical men of European birth and education, who became identified with Newport in its palmiest days as practitioners of medicine, who left on the minds of their contemporaries and of several succeeding generations the impression of very high accomplishments and very profound wisdom, and the younger natives who had the benefit of their instructions and example, sustained the character which they had established.

Among the former the names are prominent of Vigneron, Brett, Fletcher, Moffatt, Haliburton, and Oliphant. Among the latter, Senter, Mason and others.

Dr. Morbert Felicien Vigneron, or as it was latterly written and pronounced Vigneron, was born and baptised June 2, 1660, in the Parish of La Ventie, Diocese of Arras, Province of Artois, France. He is presumed to have been in Newport early in the eighteenth century, having married Susanna Pierce in 1704. He died in Newport, at a very advanced age, having practiced with a very high degree of reputation, and was succeeded by two sons and one grandson in his practice and in popular esteem, insomuch that within fifty years of this time tradition had preserved his fame, and the old French doctor was often referred to by old people as one of the luminaries not entirely forgotten.

His son, Charles Antoine Vigneron, after thirty-five years' practice in Newport, in which he fully maintained the reputation of his father, died of small-pox in New York, in 1772.

His other son, Stephen, sailed as surgeon of a privateer in the old French war, after conspicuous service at Cape Breton, and the capture of Louisbourg, and was never heard of after.

The grandson, Stephen also, was a surgeon in the Continental Army, and died of typhus on board the Jersey, prison ship, in New York.

Dr. John Brett, a graduate of medicine at

Leyden, where he enjoyed the advantage of the instruction of the celebrated Boerhaave, came to Newport about 1743 and lived here for many years. He enjoyed the reputation of a highly accomplished physician, and a man of great scholastic and literary attainments.

Dr. William Fletcher came to Newport during the Revolutionary war as surgeon in the British navy, but was transferred to the army and retired on half pay, when he entered on the practice of medicine in Newport, in 1785, and died here March 9, 1788, having, as his epitaph relates, "lived like a gentleman and died like a philosopher." Dr. Fletcher was born in Lancashire, England, in 1742, and was, therefore, at his death 46 years of age.

Dr. John Haliburton came to Newport about 1760, probably, and married January 4, 1767, Susanna, daughter of Jahleel Brenton, Esq., of Newport, sister of Admiral Jahleel Brenton, of the British Navy. This connection gave him high social position, and identified him with the wealthiest and most influential family in the Colony, and his career was a most successful and brilliant one until at an early period of the Revolution, he came under suspicion of loyalist practices and became a refugee, and passed the rest of his life in Nova Scotia, dying there in 1807, æt. 69 years. He was the father of Sir Brenton Haliburton, an eminent jurist, and for many years Chief Justice of Nova Scotia.

Dr. William Hunter, said to have been a kinsman of the distinguished brothers, William and John Hunter, of Edinburgh, was a native of Scotland, and a graduate of Edinburgh University, then considered the centre of medical light. He was born in 1731, and died at Newport, January 31, 1777, from fever incurred in hospital service. He has been reputed to have been a refugee after Culloden, but if the dates are correct, he was too young to have acquired a medical education in 1746, when the rebellion collapsed, and too young to have incurred the penalty of rebellion, but the tradition has been a very tenacious one. He is supposed to have come to Newport about 1750. He soon acquired a prominent position as a practitioner in Newport, and in 1758 was elected physician and Surgeon-General of the Rhode Island troops, and served in the unfortunate expedition to Canada under General Abercrombie, and the subsequent more successful one under General Amherst, when the fall of Montreal closed the war, and Dr. Hunter returned to his practice in Newport, which was very successful.

In 1756, Dr. Hunter delivered in the State House in Newport, the first course of anatomical lectures ever given in America. September 13, 1761, he was married to Deborah Malbone, daughter of Godfrey, Esq., of Newport, by which he established an alliance with one of the most

influential and wealthy families in the Colony, and until his death he was a prosperous and successful man.

Dr. Hunter was active and very positive in his adherence to the cause of the Crown in all the troubles preceding the Revolution, and was consequently very obnoxious to the other party, but he died while the British forces were in possession at Newport, and in the full persuasion of the final triumph of the royal cause. He was outspoken in his denunciation of those he was pleased to style "the domned Rubbels."

Dr. Thomas Moffatt, a Scotch refugee, after Culloden, came to Newport, and practiced medicine with much reputation until 1765, when he became obnoxious to the people from his activity in the enforcement of the Stamp Act, and was driven away, but returned to Newport when it was in the possession of the British, and left on their evacuation, never returning. He was a man of high reputation. Dr. Senter was a student in his office.

Among the highly distinguished medical men who made Newport their residence in the last quarter of the eighteenth century, Dr. David Olyphant should not be overlooked. He was born in Scotland, at Pitheaoles, near Perth, and was a younger brother of Lord Olyphant and was heir to his title, which he never claimed having become thoroughly Americanized. He was in the Jacobite Rebellion of 1745, and escaped and came to Charleston, South Carolina, where he practiced for many years with great success and distinction. At the commencement of the Revolution he offered his services to Congress, and was appointed Director-General of the Southern Hospitals. He removed to Newport in 1785, and married his third wife, Miss Ann Vernon, here in 1786. He died in Newport in 1804, æt. 85 years. Dr. Olyphant was an esteemed member of the Society of the Cincinnati of Rhode Island, and emphasized his devotion to American sentiments by naming his son David Washington Cincinnatus Olyphant.

Among those who were in the settlement at Portsmouth, (upon the island of Rhode Island), in its first year, 1638, were Dr. John Clark and Dr. Robert Jeffreys.

By Act of the General Court of date September 17, 1644, at Newport,

"It is ordered that Mr. Robert Jeffreys shall be authorized to exercise the function of Chirurgie."

Mr. Jeffreys was active and prominent in the affairs of the settlement, but his claim as a medical practitioner is not otherwise alluded to, and as John Clarke was a signer of the original compact, and one of the first arrivals, and was a very much more important member of the body, and is not mentioned in the public record in his medical relation, the inference is that Mr. Clarke had the authority of a European University, while

Mr. Jeffreys depended on this act of the Legislature for his license to practice, and there is almost conclusive evidence, recently obtained by Dr. Storer through exhaustive inquiries made for him by Dr. Wm. O. Priestley, of Kings College, London, that Mr. Clark, who spent many years afterward in successful practice in London, was a graduate of the University of Leyden, then the most famous school of medicine in the world. He is entered upon the registry of that University in 1635 as "Johannes Clareq, Anglus."

Singularly enough in March, 1664, the year in which the Charter of King Charles II went into force, the General Assembly passed the following Act, viz.:

"WHEREAS: The Court have taken notice of the great blessing of God, on the good endeavors of Captayne John Cranston, of Newport, both in Phissick and Chirurgery, to the great comfort of such as have had occasion to improve his skill and practice, etc. The Court doe, therefore, unanimously enacte and declare, that the said Captayne John Cranston is lycenced and commissioned to administer Phissick and practice Chirurgery throughout this whole Collony, and is, by this Court, styled and recorded, Doctor of Phissick and Chirurgery, by the authority of this, the General Assembly of this Collony."

This, it is safe to say, was the first degree of M.D. ever granted and promulgated on this Continent, and we have no means of knowing what qualifications Mr. Cranston possessed or by what means the General Assembly ascertained them.

Dr. Cranston was born in Scotland in 1625 or 1626, and appears first on the Rhode Island Record in 1644, æt. about 19 years, and died in Newport, March 11, 1680. He was very conspicuous and influential in all the affairs of the Colony, and was Governor at his death. His son Samuel was also Governor from 1698 to 1727, 29 years, also dying in the office.

Dr. John Clarke, who was one of the first settlers and a signer of the Compact, was undoubtedly the most conspicuous and important of the Rhode Island founders. He was born in 1609 and died April 20, 1676, being at the time of exodus from Massachusetts 30 years of age.

Evidently Dr. Clarke was a potential factor, and an essential element in all the events which resulted in establishing and maturing the little Commonwealth which eventually comprised the settlements of Aquidneck, Providence, and Warwick, with the gradual annexation or re-annexation of Kings Province, now Washington County, always claimed by Rhode Island, but contested by Massachusetts and Connecticut, and finally of the Eastern towns in 1747, which had been attached to the jurisdiction of Plymouth Colony, which itself had been merged in Massachusetts since 1690. In all these transactions Dr. Clarke had been an effective agent, as he was in procuring the charter of 1663, which charter, under which the Colony, and State of Rhode Island and Providence Plantations was administered until

1843, confirmed by the royal authority of Charles II, the right of liberty of conscience to all living under it, in the most formal manner, even as it had been previously established by law under the former charter. Thus did the State of Rhode Island become the first political organization among men, having as its basis of organic law this vital principle of individual freedom.

Besides being thus important in the Colonial affairs, Dr. Clarke held high professional rank as a physieian. He also was the founder and first pastor of the first Baptist Church in Newport, and it is a mooted point whether this did not antedate that in Providence, in which case it would be the first Baptist Church established in America. Dr. Clark was the faithful and diligent, and learned pastor of this Church until his death. His estate was bequeathed to three assigns for public purposes, as a perpetual trust.

Drs. Thomas and John Rodman, came to Newport in 1680; they were sons of Dr. John Rodman, of Christ Church Parish, Island of Barbadoes. Dr. John, after some years practice in Newport, went to Block Island, and after remaining there for several years, he settled on Long Island, where he has a numerous progeny. Dr. Thomas remained in Newport and died here, January 17, 1727, æt. 80 years and 16 days.

Two of Dr. Thomas Rodman's sons were physicians. Thomas lived and practiced in South Kingstown, R. I., where he has numerous descendants. Clarke remained at Newport where he died in 1752, æt. 53 years.

Two sons of Dr. Clarke Rodman were physicians, Walter and Thomas.

Dr. Walter Rodman died at Jamestown, in 1753, æt. 34 years, having practiced at Newport for fourteen years.

Dr. Thomas Rodman was born in 1726, was Freeman of the Colony in 1745. In 1759 he was elected surgeon of the Rhode Island Regiment in the service of the Crown, and in 1760 was re-elected. He was in the campaigns against the French and Indians on the Canada frontier during those two years, from which time his record is not known. So that from 1680 to 1760, not quite a century, the citizens of Newport were indebted to the Rodman family for continuous medical service. They were all esteemed members of the Friends' Society.

Among the sons of the soil who worthily succeeded the luminaries heretofore mentioned towards the close of the eighteenth century, were Drs. Senter and Mason.

Dr. Isaae Senter was born in Londonderry, New Hampshire, in 1753. Nothing is known of his boyhood. In early youth he became a student in the office of Dr. Thomas Moffatt, before spoken of as a Scotch refugee. Dr. Senter joined the Rhode Island forces, before Boston, at the beginning of the Revolution, and soon became surgeon

of a Rhode Island Regiment of the Continental line, and was in Arnold's department of Montgomery's unfortunate expedition to Quebec. In 1779 he left the service and returned to a practice which he had left in Cranston, R. I. Here he remained until 1780 when he came to Newport, and was the leading practitioner here until 1799, when he died at the early age of 44 years, having achieved a more brilliant fame, particularly as a surgeon, than has fallen to the lot of any other man in this community.

Dr. Benjamin Mason, a native of Newport, after studying with Dr. Seuter, settled in Newport, and practiced with great success until his death in 1801, æt. 40 years. Dr. Ursher Parsons described him as at the head of his profession in Newport.

The faculty has been represented in the present century, in a manner not unworthy the example given in the two preceeding ones, by a most respectable body of men, one generation of whom passed away between 1830 and 1840, viz.: Dr. William Turner, Dr. Edmund Waring, Dr. David King, and Dr. Enoch Hazard, all of whom commenced practice with the century, to be succeeded by Dr. James V. Turner, Dr. Theophilus C. Dunn, who was an early Vice-President of the American Medical Association, Dr. Daniel Watson, and Dr. David King, Jr., Dr. Samuel W. Butler, and others, including some of those still in active life, who need not be mentioned in detail. There should be named Dr. Charles Cotton, who came to Newport about 1814, and formed a link between the first and second class, dying in 1870 at the ripe old age of 81 years, an age very much beyond any of his professional contemporaries.

Having said this much of the profession, I trust a few remarks, not especially pertaining to it, may be excused.

One of the most interesting episodes in Newport history was the arrival here of the distinguished Dr. George Berkely, the author of the "Minute Philosopher," in 1728. He had left Europe with the design of establishing at Bermuda a college for the education of the American Indians. Having abandoned this plan as impracticable, he made his abode for several years at Newport, where his influence was soon felt in the inauguration of a decided advance in literary culture, which eventuated in the founding of a literary association which afterward became the Redwood Library Association, an institution which at an early period held a high rank among the American localities of literary pretensions, and which gave to Newport the advantage of a library of a high tone at an earlier time than any other American town, not the seat of a Collegiate Institution. The original books in this collection were of the highest character.

Among the beautiful spots which adorn this Island, none is more beautiful than Butts' Hill,

at Portsmouth, and none appeals as strongly to the interest of all Americans, it having been the central point (Point d'Appui) of the battle of Rhode Island, fought on the 29th of August, 1778, and pronounced by Lafayette "the best fought action of the War." The site at present is marked by the remains, remarkably well preserved, of a strong fort erected by the British, but at the time of the action in possession of the Americans, and from which the most vigorous assaults of the British and Germans were successfully repulsed by the Americans, leaving them still in possession at the close of the day. But during the night the Americans made a most successful retreat across the bay, as was said, without the loss of a man or a pound of ammunition or stores. The expected British fleet arriving next morning surrounded the Island, and but for their timely retreat not a man of the American army would have escaped.

From the fort a most superb landscape is presented comprising the East and West Narragansett Bay and Mount Hope Bay, and exhibiting very distinctly all the lines of approach and retreat.

The failure of the siege of Newport and the capture of General Piggott's army of 7,000 men, which had seemed almost assured, and was defeated only or chiefly through adverse weather, was one of the bitterest disappointments encountered by Washington during the entire war, and bore very heavily on the scattered and impoverished population of the State, and especially on the Islanders who were generally refugees dependent on the hospitality of the already overburdened denizens of the mainland, and when, after the British evacuation, they returned to their homes, universal and indiscriminate desolation had usurped the place of their thrifty and comfortable farm steads, and houses, barns, fences and orchards, and everything capable of being used as fuel had been consumed to supply the garrison and residents. No accessible portion of the mainland being in possession of the British, and the British troops and German contingent are said to have suffered excessively from want of fuel, the winters during their occupation having been exceptionally severe.

From DeWarville's travels in America," 1788, page 80 :

"I went from Providence to Newport in a packet boat. This journey might be made by land, but I preferred the water. We arrived in seven hours and a half, and during two hours we had contrary wind. This distance is thirty miles. We never lost sight of land, but it offers nothing picturesque or curious. A few houses, some trees, and a sandy soil are all that appear to the eye.

"The Port of Newport is considered as one of the best in the United States. The bottom is good, the harbor capable of receiving the largest ships and seems destined by Nature to be of great consequence. This place was one of the scenes of the last war, the successive arrival of the American, English and French armies left here a considerable quantity of money.

"Since the peace everything is changed. The solitude is only interrupted by groups of idle men standing, with folded arms, at the corners of the streets, houses falling to ruin; miserable shops, which present nothing but a few coarse stuffs, or baskets of apples, and other articles of little value; grass growing in the public square, in front of the court of justice; rags stuffed in the windows, or hung upon hideous women; everything announces misery, the triumph of ill faith and the influence of bad government. You will have a perfect idea of it by calling to mind the impression once made upon us on entering the City of Liege.

"Recollect the crowd of mendicants besieging us at every step, to implore charity; that irregular mass of Gothic houses falling to ruin, windows without glass, roofs of half uncovered; recall to mind the figures of men scarcely bearing the print of humanity, children in tatters, and houses hung with rags, in short, represent to yourself the asylum of famine, the rascality and the impudence that general misery inspires, and you will recollect Liege, and have an image of Newport."

The over-weening pride and affection, which a native Rhode Islander cherishes towards his natal soil and the time-honored traditions and institutions of the Commonwealth of his fathers, must to denizens of other States comprising many times its area and supporting many times its population, seem almost absurd, but patriotism is a sentiment which bears no relation to the magnitude of areas, or to the numerical features of populations. The Scot of the days of Bruce and Wallace yielded no tittle in his devotion to Scottish independence and in national pride to the adherents of the great monarchies of France, England, Spain, and the German Empire, and despite the overwhelming superiority of England in population, territory, and resources, defied for generations with dogged tenacity, all the power of her arms and all the guileful influence of her most astute politicians in the unstinted and unscrupulous use of her almost unlimited wealth. Corrupt as were many of the leading Scots, the great popular heart always beat responsive to the love of country and to the honor of the name of Scot. And the final union of Scotland and England was not the result of conquest on the one part and of submission on the other, but of equal and harmonious adjustment of all differences.

The circumstances surrounding the first settlement of Rhode Island and the earlier portion of its career, were such as to give a peculiar bias to the minds of the settlers, and to cultivate the tenacity of purpose and the stern energy which especially characterized the early Rhode Islanders, even when compared with the Puritan and other elements which were in no wise deficient in the same characteristics so necessary in struggling against the disadvantages of a rough and unthankful soil, a rigorous climate, and a savage and relentless population. Besides all these, the Rhode Islanders encountered from the beginning, and at every subsequent period the antagonism of the adjacent Colonies.

All three of the Settlements, Providence, Aquidneck and Warwick, were made by parties who

were refugees from Massachusetts, either expelled that jurisdiction or in fear of expulsion for the entertainment of opinions deemed heretical there, and particularly they held the opinion, which they directly promulgated and always adhered to, that in matters of belief every man is, and of right ought to be, his own judge. This doctrine, now accepted by all civilized communities, was then comparatively novel, and was long familiarly known as the Rhode Island doctrine or idea, and although not entirely new, had never so far crystalized into active power as to be enacted into authoritative form until adopted as their fundamental law by the General Assembly of Rhode Island, although understood by the settlers in their first informal agreement of settlement.

Every Rhode Islander, therefore, is peculiarly sensitive in relation to the sacredness of individual liberty, and no doubt this sentiment, in its excessive development, has often prevented the enactment of laws which may have been beneficial, but still we look upon it as calculated to have a beneficent influence, and the fact of its existence, which could hardly have failed to result from the relations referred to, will explain the excessive local feeling which belongs, of right, to a Rhode Islander.

The long delay of Rhode Island to accept the Constitution of the United States grew, in a great measure, out of this distinctive sentiment, and although unwise at that crisis argues no disparagement to Rhode Island patriotism, which has always made prompt and active response to all subsequent appeals as it had adhered to the struggle for independence under the stress of particularly severe and trying circumstances. I refer to the occupation, for a long period, of its principal town and seaport, and the suppression of its commerce, which had been its principal resource.

With the same warmth and singleness of heart, with which she has hitherto always responded to the call of duty, and with a full conception of the honor conferred on her, by your selection of her as your place of meeting on the present occasion, Rhode Island now opens its arms to welcome you, gentlemen of the American Medical Association, to all the enjoyments and conveniences which can be secured to you by willing hearts and active hands, and hoping that the most gratifying results may be derived from your deliberations, offers to you a warm greeting.

THE TREATMENT OF FRACTURES OF  
THE NECK OF THE FEMUR BY IM-  
MEDIATE REDUCTION AND  
PERMANENT FIXATION.

BY N. SENN, M.D., Ph.D.,

OF MILWAUKEE, WIS.

ATTENDING SURGEON MILWAUKEE HOSPITAL; PROFESSOR PRIN-  
CIPLES OF SURGERY AND SURGICAL PATHOLOGY, RUSH  
MEDICAL COLLEGE, CHICAGO, ILL.

The treatment of a fracture of the neck of the femur is always a source of anxiety to the surgeon. In many instances the diagnosis is attended by unusual difficulties and not infrequently a fracture of this kind is overlooked, even after what appears to have been a thorough examination, while at other times, for want of a correct diagnosis, patients have been submitted to a long and debilitating treatment when no fracture existed. Patients suffering from this injury are with few exceptions advanced in years and liable to succumb to complications incident to prolonged confinement in bed. The marantic changes in the tissues of the aged and in persons rendered prematurely old by hereditary or acquired causes are known to be antagonistic to a rapid repair of such an injury, while at the same time the anatomical conditions at the seat of fracture are such as are well calculated to retard, if not to prevent, the production of callus. With few exceptions our surgical text books and special work on fractures continue to advance the same ideas that have been prevalent for centuries concerning the process of repair in fractures of the neck of the femur, and assert that bony union is only possible if the line of fracture is completely, or at least, partially outside of the limits of the capsular ligament. Teachers and authors are so positive in their assertions that if the fracture is entirely intra-capsular a pseudo-arthritis is inevitable, that many cases of partly extra-capsular fractures have been treated on the expectant plan the same as intra-capsular fracture, and only too often with the same unsatisfactory result. The time has come when it is no longer admissible to make such a distinction in the lecture room, the text books or at the bedside. Experience and experimental research have demonstrated that the proximal fragment, in case the line of fracture is entirely intra-capsular, does not only retain its vitality, but if placed in accurate contact with the opposite fragment, either by impaction or by mechanical fixation it takes an active part in the production of callus.

In a paper read at the meeting of the American Surgical Association, in 1883, ("Fractures of the Neck of the Femur, with Special Reference to Bony Union after Intra-capsular Fracture," Transactions of the American Surgical Associa-

tion, vol. 1), I gave an account of fifty-four cases collected from different sources of bony union after intra-capsular fracture and in most of them the proofs in support of the assertion were so convincing that even skeptics on this subject would find it difficult to give to them a different interpretation. In the same paper I recorded the results of my own experimental work undertaken for the special object of demonstrating, if possible, that bony union after intra-capsular fracture is so seldom obtained, not so much on account of the anatomical peculiarities of the parts involved in the fracture as the inefficient treatment which is usually resorted to in its treatment. In the animals subjected to experiment the fracture was produced by making multiple punctures with a small drill through the neck of the femur entirely within the limits of the capsular ligament and fracturing the balance of the bone by forcibly rotating the femur inwards. Twenty-three fractures in so many different animals thus produced were treated on the expectant plan, or by simple fixation with a plaster-of-Paris dressing. The animals were killed from four weeks to three months after fracturing the bone, and the seat of fracture was carefully examined in every instance, but in none of them was I able to find any evidences of bony union. The best result obtained by this method of treatment was pseudo-arthritis by the interposition of a short ligament between the fractured ends. Discouraged by the many failures I finally resolved to secure accurate coaptation of the fragments by drilling a hole from the trochanter major through the entire length of the neck and well into the head and fastening the fragments together with an aseptic iron, bone or ivory nail. Eight such experiments were made on cats. In two suppuration followed the operation. In the rest bony union or union by an exceedingly short ligament without any displacement of the fragments was obtained. I will quote only two of the experiments for the purpose of illustrating the method of procedure and of showing the condition and appearance of the bone after permanent union by callus.

*Experiment 27.*—Adult Maltese cat; subcutaneous fracture of left femoral neck; fixation of fragments by means of bone nail made from compacta of tibia of an ox. Animal killed fourteen weeks after operation. Neck of femur only slightly shortened; capsular ligament nearly normal; ligamentum teres intact; vertical section shows a slight curve in the upper portion of the neck; the head being slightly depressed. Perfect and complete bony union, the spongiosa being restored nearly to its normal condition. No traces of bone nail or perforation.

*Experiment 32.*—Young cat; subcutaneous fracture of neck of right femur, direct fixation of fragments with bone nail. Animal killed four months after operation. During life function of

the joint was perfect; vertical section through the head; neck and upper portion of shaft, shows that the line of fracture must have been entirely within the capsule, as the capsular ligament and bone outside of it presented a perfectly normal contour and appearance. Accurate measurements show only a very slight shortening of the neck; the osseous tissue composing the interior of the neck more dense than in the opposite bone. Spongiosa restored to nearly its natural perfection. No traces of track of perforation or bone nail.

In no case did I feel crepitation after the fracture more distinctly than in this instance, and the sudden giving way of the bone the moment it was fractured was well marked, and was heard by all of the assistants, and as the post-mortem examination shows a perfect restoration of the continuity of the bone, I am firmly convinced that this specimen represents a typical and perfect recovery of union by bone after intra-capsular fracture of the neck of the femur. The results obtained by immediate trauifixion of the fragments stand in direct contrast to those treated by external fixation. Bony union, or union by short ligament, was the rule, non-union the exception. In the treatment of all fractures the two cardinal indications are: *Firstly*, to bring the fractured surfaces into accurate coaptation as soon as possible after the accident, and, *secondly*, to maintain uninterrupted approximation by permanent immobilization. In these respects the treatment of fractures is governed by the same rules as the treatment of wounds of the soft parts. In the repair of all injuries the severed tissues should be brought as nearly as possible in the same relative position they occupied in their normal condition and to retain them in such position by temporary mechanical measures until the completion of the reparative process. By following this rule the normal regenerative resources inherent in the tissues are taxed only to a minimum extent and definitive healing is obtained in the shortest possible space of time. As union between the divided or severed parts can only take place by the interposition of new material, the product of a regenerative process in the tissues at and in the immediate vicinity of seat of trauma, and as this process presupposes the existence of a connecting bridge of new blood vessels, it is evident that the length of time required to secure union will be greatly modified by the width of the intervening space. It is somewhat strange that the customary treatment of fractures of the neck of the femur which has governed the practice of surgeons from time immemorial, still commands the confidence of the profession. For centuries these fractures have been treated by some kind of extension and imperfect immobilization. The favorite treatment of to-day consists of extension by means of the weight and pulley as devised by Gordon Buck, and fixation of the limb by a long

splint or two sand bags. The extension is applied for the purpose of counteracting muscular contraction, the cause of the shortening of the limb. If we consider the number and strength of the muscles which are inserted in the lower fragment, and which are the direct cause of the shortening, we can imagine the force requisite to overcome the longitudinal displacement. At best permanent extension by weight and pulley corrects the shortening only gradually and always imperfectly and never secures immediate reduction, the first and most important indication in the treatment of any fracture. As the upper fragment is short, sometimes not reaching beyond the niveau of the cotyloid cavity, is deeply located and not parallel to the long axis of the lower fragment, but nearly at a right angle to it, all means of fixation short of complete immobilization of the pelvis and the lower fragment upon it must fail in securing uninterrupted coaptation and perfect immobilization. The result obtained by the customary treatment have been such that no better proof need be advanced to demonstrate its inadequacy. The long confinement in bed which it necessitates has often proved a direct cause of death. Bony union of fractures within the capsule has only occurred in cases where impaction had taken place and where this means of fixation was allowed to remain undisturbed until union was completed, in all other cases a pseudoarthrosis proved to be the unavoidable result. In fractures outside of the capsule healing with shortening of an inch has always been considered an excellent result, and more frequently the shortening was in the neighborhood of two inches. The treatment by weight and pulley extension and splint fixations requires constant watchfulness on the part of the surgeon and those who are in direct charge of the patient. Extension continued for two or more months not infrequently is followed by serious, if not permanent, damage to the structures of the knee joint.

It is my purpose on this occasion to call your attention to the advantages to be derived from the treatment of fractures of the neck of the femur by immediate reduction and permanent fixation as compared with the treatment by the usual methods. The treatment I shall describe is equally well adapted for intra- and extra-capsular, impacted and non-impacted fractures. As it is no longer necessary, from a practical standpoint, to make a distinction between an intra- and extra-capsular fracture, I will only allude to a few diagnostic signs which indicate the existence of a fracture through the neck of the femur which should be sought for, and carefully considered before a positive diagnosis is made.

#### SYMPTOMS AND DIAGNOSIS OF FRACTURE OF THE NECK OF THE FEMUR.

Displacement after fracture through the fem-

oral neck is due either to the fracturing force, muscular contraction or simple gravitation. In incomplete and impacted fractures it is caused entirely by the fracturing force. A number of incomplete fractures have been reported by König, King, Jackson, and Billroth. These fractures are produced by crushing, not overbending. If the force is transmitted through the long axis of the femur the lower portion of the neck gives way and Adam's arch penetrates the cancellated tissue of the neck to a certain distance, thus shortening the lower border of the femoral neck, a condition which would give rise to slight adduction, but no shortening of the limb, and the upper border of the trochanter major will be found in normal position in reference to Roser-Nélaton's line. If incomplete fracture take place at the expense of the posterior portion of the neck the limb will retain its normal length, but the posterior margin of the trochanter major would be displaced slightly in a posterior direction and would be somewhat less prominent than on the opposite side. If in an exceptional case the fracturing force should be transmitted through the trochanter major in an opposite direction and would crush a portion of the bone on the anterior surface of the neck, the slight deformity produced would be the same, only that the trochanter would be found rotated in an opposite direction. In all incomplete fractures then, no shortening exists and the upper margin of the trochanter major corresponds to the Roser-Nélaton line. In complete but impacted fractures the displacement is caused entirely by the fracturing force and is commensurate with the amount of bone tissue crushed at the seat of fracture. As the fracture in these cases is complete, more or less shortening is always present. A fall upon the foot or knee, as a rule, will fracture the neck at its narrowest portion, and, if the fracture is complete, no impaction will take place, unless it follows as a secondary occurrence from transmission of force through the trochanter major. In such cases the impacting force acts at a right angle to the fracturing force. Experiments and clinical observations have shown that the majority of fractures of the femoral neck are produced by force applied in the direction of the axis of the neck by falls upon the trochanter major. It is also well established that in most instances the neck gives way at its trochanteric portion, and that the posterior wall is crushed or fractured first, impaction of the posterior wall is therefore the rule. Besides shortening, an impacted fracture of the neck is always attended by slight rotation of the limb in the direction of the impaction. For instance, if the force is applied laterally through the trochanter, and, as is usually the case, from before backwards the posterior wall fractures first and impaction takes place here, the degree of rotation of the limb in an outward direction will be

an indication of the extent to which impaction has taken place. In very exceptional cases, if, as has happened in a few instances, the fracturing force is applied against the posterior border of the trochanter major, the anterior wall of the neck is fractured first and impaction takes place at this point, an occurrence which is always indicated by the limb being rotated in an inward direction. In impacted fractures the upper margin of the trochanter major will always be found above the level of Roser-Nélaton's line, the outer surface of the trochanter is less prominent than on the opposite side and its posterior border is displaced backwards in the most common form of impaction with outward rotation of the limb. In complete fractures without impaction the displacements are due to active and passive causes. The shortening results from muscular contraction and increases with the restoration of muscular action, while the rotation outwards of the limb is due to the tendency of the limb to fall in this direction when in a condition of complete repose.

*Method of Examination.*—Injuries about the hip-joint of sufficient intensity to fracture the femoral neck in persons advanced in years should always be examined with the utmost care for evidences of fracture. Whenever possible a positive diagnosis should be made at the first examination. In some cases the symptoms are so characteristic that a correct diagnosis can be made almost on first sight, while in other instances all diagnostic resources must be exhausted before a correct idea of the nature of the injury can be obtained. To make a thorough examination all clothing as far as the chest must be removed and the patient placed upon an even, smooth, unyielding surface, either upon a table or the floor. Inspection will reveal the presence or absence of a bruise over the trochanter major. If present the location of the superficial contusion will indicate the direction of the fracturing force. Suggillations about the hip are suggestive of a deep-seated injury, and not infrequently they make their appearance over the groin and along the inner side of the thigh in a few days after a fracture of the neck of the femur. If the limb is strongly rotated outwards, and by its position dislocation of the hip-joint can be excluded, it is more than probable that the femoral neck is fractured. In all cases of fracture of the neck, there is an appreciable fulness in the fold of the groin corresponding to the seat of the fracture. This swelling is caused by the hinge-like projection of the anterior portion of the neck, effusions of blood or inflammatory products, and, lastly, by the overriding or impaction of the fragments. When impaction has taken place at the base of neck, the trochanteric portion of the femur is enlarged from implantation of the upper fragment. More swelling is present in extra than intra-capsular fractures, as in the former there is more

hæmorrhage and the bone injury is more extensive. Another witness which can be elicited by inspection in cases of fracture through the femoral neck, is a slight depression between the great trochanter and the crest of the ilium, a change in contour caused by relaxation of the fascia lata, as was first pointed out by Dr. Allis. This sign is most marked when the patient is placed in the erect position. The symptoms which have been elicited by inspection and gentle palpitation must be verified by careful measurements. The information furnished by measurements carefully made can be relied upon in arriving at positive conclusions concerning the nature of the injury. It is not only superfluous but positively harmful to search for positive symptoms of fracture, crepitus, preternatural mobility of fragments, and new point of motion, in these cases; all manipulations during the examination of a supposed fracture in this locality should be made with the utmost care and gentleness. The search for crepitus and other positive symptoms of fracture has been the cause of incalculable harm. In many instances careless handling of the limb has resulted in disjunction of impacted fractures, or in tearing of periosteal or ligamentous bands, thus removing the conditions upon which rested the possibility of obtaining osseous union by the interposition of a short ligamentous band. In every case care is to be taken not to disturb the parts at the seat of injury for the purpose of making a diagnosis; it can never become necessary to administer an anæsthetic for the purpose of making a so-called *thorough examination*. Our diagnosis should depend on the presence or absence of the three most important symptoms—position of the trochanter major, shortening and eversion. A line drawn from the tuberosity of the ischium to the anterior superior spinous process of the ilium is called the Roser-Nélaton line, and with the trochanter major in its normal position and relations marks its upper edge. If the measurements show shortening, and the femoral neck is fractured, the upper border of the trochanter major will be found displaced beyond the Roser-Nélaton line to the extent of the actual shortening. It has recently been shown by Wight, Hamilton, Gurson, and others that inequality in the length of the lower limbs is a rather common occurrence, consequently in order to eliminate sources of error, it becomes necessary to ascertain the presence of asymmetry, should such exist, in applying measurements in the diagnosis of a fracture of the neck of the femur. For the purpose of avoiding errors, which might accrue from asymmetry of the lower extremities, Wight directs that the following measurements should be taken: (1.) Inside measurements from the superior anterior spines of the ilium to the lower ends of the internal malleoli. (2.) Outside measurements from the superior anterior spines of the ilium to the

lower ends of the external malleoli. (3.) Measurements from the tops of the great trochanters to the lower ends of the external malleoli. (4.) Measurements from the bases of the tibiæ to the lower ends of the internal malleoli. (5.) Measurements from the superior anterior spines of the ilium to a line drawn transversely in front between the top of the great trochanters. These measurements give the length of the femur and tibia on each side as well as the entire length of both limbs, and if asymmetry of any of the bones exists this fact is easily determined. If actual shortening is found the existence of a fracture of the femur below the hip-joint is excluded by ascertaining the exact relation of the great trochanter to the Roser-Nélaton line, if the trochanter is found displaced upwards to the extent of the shortening and other symptoms point to fracture, the diagnosis of a fracture through the femoral neck may be considered as established. In very fleshy persons the landmarks which serve as points from which the measurements are made are not well-defined and not easily located, and it is on this account advisable to fix the location of each as accurately as possible and indicate it on the surface by a pencil mark before any of the measurements are made. The best instrument for making the measurements is a steel tape-line, with feet and inches marked on one side, and centimetres and millimetres on the other. Eversion is readily detected by inspection. In impacted fractures it may be very slight and a sudden or gradual increase of these displacements, days, week, or months after the accident, signifies that disengagement of the fragments has taken place, an accident probably caused by inflammatory osteoporosis and imperfect immobilization. If the surgeon has demonstrated by his examination that a fracture exists, the presence of impaction can be readily ascertained by gently rotating the limb upon its axis and by making slight traction; if these manipulations affect the head of the bone, impaction has occurred, and every care should be exercised to preserve the mutual fixation of the fragments. Unimpacted fractures of the neck of the femur seldom give rise to any difficulty in diagnosis. The symptoms attending them are so well marked that a correct conclusion can be reached without causing needless suffering or inflicting additional injuries in searching for any of the positive signs.

*Treatment.*—The treatment I shall advocate in fractures through any portion of the femoral neck consists in the fulfillment of two principal indications: (1.) Immediate reduction. (2.) Permanent fixation. The first part of the treatment, the adjustment of the fragments, is of course only necessary in non-impacted fractures. In impacted fractures no attempt should be made to correct any of the displacements, as the interlocking of the fragments secures the most favor-

able conditions for bony union to take place. It is not too much to assert that if the impaction in such cases can be maintained until the reparative process is completed, union by callus would be the rule, and non-union the exception. In all intra-capsular fractures, union is effected exclusively by the production of an intermediate callus, from the broken surfaces; nature's splint, the external or provisional callus, for well-known anatomical reasons, is always wanting, hence the mechanical support which is requisite to maintain uninterrupted coaptation has a more important and prolonged application than in the treatment of fractures in other localities. The time required for bony union to take place in fractures of the femoral neck is an unusually long one. Gurlt fixes the time at from 56 to 207 days, and the average duration at 84 days. Dupuytren estimates the time from 100 to 120 days, and states that it has been customary at the Hôtel-Dieu to keep these patients in bed for 80 to 100 days. There can be no doubt that many cases, which promised well from the beginning, terminated unfavorably from failure on the part of the surgeon to secure efficient means of fixation or by abandoning the treatment too early. An impaction may become disengaged after a few weeks spontaneously or by a slight movement of the patient if the fragments are not immovably fixed by some efficient external mechanical support. To guard against such an occurrence, the retentive measures should not be removed for at least 80 to 100 days. In impacted fractures the fragments have been placed in the best possible condition for bony consolidation, and the object of treatment consists simply in preserving the mutual penetration for a sufficiently long time to obtain restoration of the continuity of the bone. Permanent fixation of an impacted fracture in the position in which it has been placed by the accident is necessary for the following reasons:

1. It prevents disengagement of the fragments.
2. It obviates secondary shortening and eversion during the stage of interstitial absorption which attends inflammatory osteoporosis.
3. By keeping the injured parts at rest, it serves as a prophylactic measure against the accession of arthritis and para-arthritis.
4. It enables the patient to leave the bed any time after the dressing has been applied, and thus guards against decubitus, hypostatic pneumonia, and other affections incident to prolonged confinement in bed.

The advantages arising from immediate reduction and permanent fixation in fractures of the neck of the femur are the following:

(a.) The untorn portions of the joint structures are replaced at once into their normal relations; a procedure which cannot fail to influence favorably the circulation in vessels which may have escaped injury.

(b.) The sharp and irregular margins of the broken surfaces act as irritants to the surrounding soft tissues; immediate reduction, by placing the fractured surfaces at once into mutual coaptation, acts as a preventive agent against the superintention of undue inflammation in and around the hip-joint.

(c.) With coaptation the process of repair is initiated at once, the blood and exudation material between the fragments act as a temporary cement substance, and at the same time serve a useful purpose in re-establishing the interrupted circulation.

(d.) Perfect reduction and permanent fixation prevent muscular spasm and diminish pain.

My experimental work convinced me so strongly of the not only possibility, but the probability, of obtaining bony union in cases of intra-capsular fractures, provided the fractured surfaces are kept in uninterrupted contact for a sufficiently long time, that I was led to suggest what justly appeared at the time as heroic measures in securing this end. It appeared to me impossible in cases where no impaction had taken place to insure sufficient immobilization of the fragments without some direct means of fixation. I suggested at that time the advisability of immobilizing the lower fragment by means of a sharp steel pin, regulated by a set screw passing through the centre of a curved steel bar, incorporated in the plaster-of-Paris splint over the fenestrum, in such a way that the sharp point of the pin would perforate the soft parts over the centre of the great trochanter, and by penetrating a small distance into the bone, could make the necessary lateral pressure and secure perfect immobility of both fragments. As still a more direct means of fixation of both fragments, I advocated that in some cases it would be justifiable to secure transfixion of both fragments by an ivory or bone nail which was to be driven through a perforation made with a drill, from the outer surface of the great trochanter through the centre of the neck and well into the head of the bone. The result of my experiments convinced me that this means of fixation answered an admirable purpose in placing the fragments in a position where union by callus could take place. The specimens illustrating this treatment demonstrated that such nails, if aseptic, and in aseptic tissues, are completely removed by absorption during the time required for bony union to take place. These suggestions were dictated by an honest conviction that any less direct measures would fail in accomplishing the desired result. It is only natural that this plan of treatment was objected to as being utterly inapplicable in most cases, and too heroic in all. Clinical experience has since satisfied me that these direct measures are unnecessary, and that the same object can be obtained by well regulated lateral pressure in the direction of the axis of the

femoral neck combined with perfect fixation of the lower fragment upon the pelvis. The influence exercised by impaction in determining the ultimate result in fractures within the capsule of the hip-joint, has been repeatedly alluded to. Many fractures of the femoral neck are kept from becoming displaced for a variable period of time, by interlocking of the denticulated broken surfaces, a condition which has been termed by Bigelow "rabbeting." Believing that the surgeon should imitate the reparative resources of nature wherever it is possible to do so, it occurred to me that artificial rabbeting could be produced in all cases by uninterrupted lateral pressure. It is not difficult to conceive that if the fractured surfaces are placed as accurately as possible in apposition, lateral pressure would effect perfect approximation and a mutual interlocking of the fragments. Lateral pressure thus applied is one of the most efficient means in preventing secondary, lateral and longitudinal displacements. Pressure, to be effective, must be applied in the direction of the broken neck, that is, directly over the trochanter major, and in such a manner as not to interfere with the superficial circulation. Pressure with belts and strips of adhesive plaster encircling the whole pelvis, can exert but little, if any, influence on the fractured bone, at the same time it impedes the superficial circulation. In the more recent cases of fracture of the neck of the femur that have come under my observation, I have pursued the following plan of treatment.

The patient is dressed in well-fitting knit drawers and a thin pair of stockings. For strengthening the plaster-of-Paris dressing over the joints, and at other points where greater strength is required oaken shavings are placed between the layers of plaster, these small thin splints greatly increase the durability of the dressing without adding much to its weight. The bony prominences are protected with cotton before the plaster-of-Paris dressing is applied. The drawers and stockings furnish a more complete and better protection to the skin than roller bandages. Usually about twenty-four plaster-of-Paris bandages are required for a dressing. The fractured limb is first encased in the dressing as far as the middle of the thigh, when the patient is lifted out of bed by two strong persons, the physician supporting the limb so as to prevent disengagement of the fragments if the fracture is impacted, and to guard against additional injuries in non-impacted fractures. The patient is placed in the erect position, standing with his sound leg upon a stool or box about two feet in height; in this position he is supported by a person on each side until the dressing has been applied and the plaster has set. A third person takes care of the fractured limb which is gently supported and immovably held in impacted fractures until permanent fixation has been secured by the dressing.

In non-impacted fractures the weight of the fractured limb makes auto-extension which is often quite sufficient to restore the normal length of the limb; if this is not the case, the person who has charge of the limb makes traction until all shortening has been overcome, as far as possible, at the same time holding the limb in a position so that the great toe is on a straight line with the inner margin of the patella and the anterior superior spinous process of the ilium. In applying the plaster-of-Paris bandages over the seat of fracture, a fenestrum, corresponding in size to the dimensions of the compress with which the lateral pressure is to be made, is left open over the great trochanter. To secure perfect immobility at the seat of fracture, it is not only necessary to include in the dressing the fractured limb and the entire pelvis, but it is absolutely necessary to include the opposite limb as far as the knee, and to extend the dressing as far as the cartilage of the eighth rib. The splint, which is represented by figure 1, is incorporated in the plaster-of-Paris

FIGURE 1

dressing, and must be carefully applied so that the compress composed of a well-cushioned pad, with a stiff unyielding back rests directly upon the trochanter major, and the pressure which is made by a set screw is directed in the axis of the femoral neck. The set screw is projected by a key which is used in regulating the pressure. Lateral pressure is not applied until the plaster has completely set. If the patient is well supported and the fractured limb is held immovably in proper position, but little pain is experienced during the application of the dressing. Syncope should be guarded against by the administration of stimulants. As soon as the plaster has sufficiently hardened to retain the limb in proper position, the patient should be laid upon a smooth, even mattress, without pillows under the head, and in non-impacted fractures the foot is held in a straight position, and extension is kept up until lateral pressure can be applied. The lateral pressure prevents all possibility of disengagement of the fragments in impacted fractures, and in non-impacted fragments it creates a condition resembling impaction by securing accurate apposition and mutual interlocking of the uneven fractured surfaces. No matter how snugly a plaster-of-Paris dressing is applied, as the result of shrinkage in a few days it becomes loose, and

without some means of making lateral pressure it would become necessary to change it from time to time in order to render it efficient. But by incorporating a splint, as shown in figure 1, in the plaster dressing (figure 2) this is obviated, and the lateral pressure is regulated from day to day by moving the set screw, the proximal end of which rests in an oval depression in the center of the pad. From time to time the pad is removed and the skin washed with diluted alcohol for the purpose of guarding against decubitus.

FIGURE 2.

*After-Treatment.*—If the application of the dressing, as just described, is a tedious, laborious and difficult task, it will prove a rich compensation for physician and patient during the after-treatment. I have never found it necessary to apply more than one dressing. If the fracture is properly reduced and the limb fixed in normal position in the dressing, then the only thing that requires watchful attention is the regulation of the lateral pressure. The patient can move himself in bed and can lie on the back, face, and on either side, and can be taken out of bed and, if the weather is favorable, outdoors daily if desirable, without pain or risk of displacement of the fragments. If necessary, a patient in such a dressing could be transported great distances without

any immediate or remote risks. The impunity by which the patient can change his position, the benefits to be derived from outdoor fresh air, are advantages which cannot be obtained by any other treatment, and to them must be attributed an important influence in the prevention of a number of the fatal complications which have so often figured as causes of death in patients suffering from fracture of the femoral neck. If the dressing has been well applied, and more especially if the precaution has been followed to protect the bony prominences with a layer of salicylated cotton, there is little or no danger of the formation of excoriations. At the expiration of eighty to one hundred days, the time required for bony union to take place, the dressing is removed, but the patient should be cautioned not to step on the limb until the end of the fourth or sixth month, when union will be sufficiently firm to sustain the weight of the body. As soon as the dressing is removed passive motion should be made, and the nutrition and function of the limb promoted by massage and, if considerable muscular atrophy is present, the use of the faradic current.

During the last six years the following cases of fracture of the neck of the femur have come under my observation, and were treated by immediate reduction and permanent fixation as detailed in this paper. A number of the cases occurred in the practice of other physicians, and I was only called in to apply the dressing. I desire in this place to express to them my sense of obligation for their permission to use the material in the preparation of this paper.

#### CASES OF FRACTURE OF THE NECK OF THE FEMUR TREATED BY IMMEDIATE REDUCTION AND PERMANENT FIXATION.

*Case 1.*—Female, æt. 68, in fair general health, slipped on the sidewalk and fell upon the right hip. The examination made a few hours after the accident revealed a contusion over the trochanter major, some swelling about the region of the hip-joint, limb everted, shortening of  $1\frac{1}{4}$  inch. The displacement of the great trochanter above Roser-Nelaton's line corresponded with the extent of the shortening. No impaction. Crepitus elicited by the slightest movement of the limb. Anatomical diagnosis: Fracture of the neck of the femur partially within and partially without the capsular ligament. In this case reduction was made by placing the patient upon a pelvic rest and making extension. The limb could be brought down to within  $\frac{1}{4}$  inch of its normal length, and in this position, with the foot in proper line, it was fixed in the plaster-of-Paris dressing, and as soon as the plaster had become firm lateral pressure by means of the pad and set-screw was applied. The patient suffered but little pain at any time, and could roll herself in bed from one side to the other with ease. The dressing was removed after three

months, when it was ascertained that bony union had been obtained with  $\frac{1}{2}$  inch of shortening and the limb in good position. Passive motion and massage were now made daily and the patient was allowed to walk on crutches. Four months after the accident she was able to walk with the aid of a cane, and three months later she required no further mechanical support. At the end of a year recovery was complete and she could walk nearly as well as before the accident.

*Case 2.*—Male, æt. 65 years. Patient is somewhat anæmic and presents evidences of senile marasmus. Fell from a ladder a distance of about 6 feet directly upon his left side. No external contusion, and swelling over anterior aspect of hip-joint slight. A number of careful measurements revealed  $\frac{3}{4}$  of an inch of shortening. Foot moderately everted. No impaction. Gentle traction upon the limb and slight rotation produces crepitus. After fractured limb was encased in plaster as far as the knee patient was made to stand with the sound limb upon a stool and was supported on each side by an assistant, while a third person made traction until the shortening was nearly corrected, and with the foot in proper position the fixation dressing was applied. Lateral pressure was applied the next day and was kept up carefully for eighty-five days, when the dressing was removed. A careful examination showed that bony union had taken place, and that the shortening did not exceed  $\frac{1}{3}$  of an inch. The patient used crutches for six weeks, later a cane for a few months longer, and at the end of a year he walked well without any support and with only a slight limp.

In this case the symptoms after the accident pointed to a fracture of the neck of the femur involving more of the bone within than without the capsular ligament. Only a slight amount of callus could be found behind the posterior margin of the great trochanter.

*Case 3.*—Female, 58 years old. Senile marasmus well marked. Patient stumbled and then fell on right side. A few hours after accident the right foot was found everted and the limb shortened  $\frac{2}{3}$  of an inch. No impaction. Right groin considerably swollen. Trochanter major displaced backwards and upwards. Probable seat of fracture partly within and partly without the capsule. Reduction was effected by auto-extension and traction upon the limb. After the limb was immobilized in the dressing the foot was in normal position and apparently little or no shortening. Fixation and lateral pressure were continued for three months. On removal of the dressing the union was found firm with  $\frac{1}{2}$  inch of shortening. Patient used crutches for three months. Stiffness in the hip-joint was only overcome by regular active and passive exercise and massage continued for a long time. At the end of eight months the patient was able to take care of her household,

and the function of the limb was nearly restored. Measurements made at this time showed that the shortening had not increased.

*Case 4.*—Male, 50 years old, prematurely old, the result of intemperate habits. Patient slipped and fell on the doorsteps, fracturing the left femoral neck. Considerable swelling at the seat of fracture. Foot strongly everted, shortening  $1\frac{1}{4}$  inches. No impaction. Trochanter major less prominent than on the opposite side and displaced upwards above Roser-Nélaton's line  $1\frac{1}{4}$  inches. No impaction. On making extension and gently rotating the limb crepitus can be distinctly felt. Reduction and immobilization in the usual manner. The second day the patient had an attack of delirium tremens. During the maniacal excitement he tossed himself in every direction and the nurses were kept busy in preventing him from demolishing the dressing. It was during this attack that the fixation dressing and the lateral pressure gave evidence of their efficiency in maintaining uninterrupted coaptation under the most unfavorable circumstances. Under the use of narcotics the patient became rational and quiet on the third day. The dressing had to be repaired in several places. Subsequently the progress of the case was favorable. The dressing was removed after ninety days, when the fracture was found firmly united with nearly an inch of shortening; considerable callus in front of and behind the trochanter. The patient was soon able to walk around on crutches, but I have been unable to obtain any reliable information as to his condition since.

*Case 5.*—A female, weighing nearly 200 lbs., was thrown out of a buggy and fell upon her left side. After she recovered from the immediate effects of shock she found that she could not use her left leg. Two physicians who examined the patient soon after the injury suspected a dislocation of the hip, but made no attempts at reduction. When I examined her the next day I found marked eversion of the foot, and a number of measurements made showed  $\frac{1}{2}$  inch of shortening. The great trochanter had been displaced beyond Roser-Nélaton's line to the same extent, and appeared to be less prominent than on the opposite side. No swelling in the groin or posterior aspect of the hip-joint. On gently rotating the limb the great trochanter described a smaller circle than on the opposite side, and the movements affected the head of the femur. Slight traction had no effect in diminishing the shortening. The diagnosis of intracapsular impacted fracture was based upon these symptoms, and every precaution was exercised not to cause disjunction of the fragments during the examination and the application of the dressing. As I was anxious to maintain the impaction during the required time for bony union to take place, the patient was treated in the same manner as in the

preceding cases, only that no attempts were made to overcome the shortening or to correct the other displacements. Lateral pressure was applied in a line with the axis of the outer portion of the femoral neck for the purpose of maintaining the impaction during the stage of inflammatory osteoporosis. The dressing was not disturbed for three months, when it was removed and the limb was found in the same position as when it was applied. The shortening had not increased. The patient was cautioned not to use the limb for another three months and to depend in walking entirely on crutches. For a long time the movements in the hip-joint were impaired, undoubtedly the result of a traumatic plastic inflammation of the structures of the joint. Passive motion and massage succeeded in restoring the normal functions of the joint. At no time could any callus be felt, which must be considered as another proof that the fracture was intracapsular. At the end of a year the patient walked nearly as well as before the accident.

*Case 6.*—A man, 65 years of age, slipped on an icy sidewalk and fell in such a manner that the right femoral neck was fractured. A few hours after the accident a considerable swelling had formed in the groin. Contusion over the great trochanter; eversion so marked that the outer margin of the foot rested on the mattress. Shortening  $1\frac{1}{2}$  inch. No impaction. Crepitus on slightest motion of limb. Diagnosis non-impacted extracapsular fracture of the neck of the femur. Reduction was accomplished by auto-extension and traction on the limb. Fixation by means of plaster-of-Paris dressing and lateral pressure. Patient was relieved of pain as soon as the dressing had been applied and remained in good health during the entire treatment, which was continued for seventy-five days, when the dressing was removed. Bony union with  $\frac{3}{4}$  of an inch of shortening. A large mass of callus on each side of the great trochanter could be distinctly felt. Crutches were used for four months. At the end of a year walked without any support and with only a slight limp.

*Case 7.*—A strong, healthy blacksmith was thrown from a buggy which was upset by an unruly horse. He fell in such a manner that his full weight came upon the right hip. Immediately after the fall he found that he was unable to use the right leg. He was conveyed in a carriage to his home some three miles distant, and examination two hours later revealed the following: superficial abrasion of skin over the great trochanter; marked eversion of foot. Shortening  $1\frac{1}{2}$  inches; tip of trochanter some distance above Roser-Nélaton's line; right femur  $17\frac{1}{4}$ , and left femur  $17\frac{1}{4}$  inches in length. Crepitus on extension and rotation of the limb inwards. New point of motion at seat of fracture very evident. Pain is referred to point immediately behind the

great trochanter. Considerable swelling in the groin and behind the great trochanter. The injury was diagnosticated as an extracapsular non-impacted fracture. Reduction by auto-extension was made on the third day and the fracture immobilized by plaster-of-Paris dressing in which the splint was incorporated for making lateral pressure. Patient suffered but little pain after the dressing was applied. The dressing was not removed for twelve weeks, when a large mass of callus was found behind and in front of the great trochanter, which for quite a long time seemed to impair the movements of the joint. With the disappearance of the callus the functional result improved. The fracture healed by bony consolidation with an inch of shortening. In six months he dispensed entirely with the use of crutches, and with a high sole on right boot to make up for the shortening of the limb he walks with only a very slight limp. In twelve months he was able to attend to his business, even to horse-shoeing, and has since, aside from the slight lameness, suffered no inconvenience from the accident.

*Case 8.*—An invalid lady, 61 years old, while descending three low steps caught the left heel in the skirt of her dress and fell, striking on the left hip. Examination soon after revealed the following *status præsens*: Dark blue discoloration of skin over the outer and posterior aspect of the great trochanter and from 2 to 3 inches below the hip-joint indicates the point where the fracturing force was applied. Slight eversion of foot. No swelling in groin or posterior aspect of hip-joint. Tip of great trochanter  $\frac{1}{2}$  inch above Roser-Nélaton's line. On making measurements from anterior superior spine of the ilium to the internal malleolus no shortening could be detected, but the apparent discrepancy between the result obtained by these measurements and the Roser-Nélaton's test-line was subsequently explained by the other measurements, which showed asymmetry of the femora, the femur on the injured side being  $\frac{1}{2}$  inch longer than its fellow on the opposite side. Left trochanter rotates on a shorter radius of a circle than the right. Pain in the hip increased by pressure over the great trochanter. Patient is able to elevate the limb about 2 feet from the bed, but all such efforts aggravate the pain. The symptoms in this case, as well as the manner in which the injury occurred, pointed directly to an impacted intracapsular fracture of the neck of the femur. In order to secure the benefits of long continued impaction during the process of repair immobilization of the fracture was secured by a plaster-of-Paris dressing and splint for lateral pressure. The general condition of the patient was not impaired by this kind of treatment of the fracture, and when the dressing was removed eight weeks after its application the limb was found in the same position as after the accident. The patient was directed to rely on crutch-

es for a number of weeks and then to use the limb cautiously. At the end of five months she could walk without a cane and with an almost imperceptible limp.

The treatment I have described I recommend for adoption in all cases where there is a reasonable hope that by it a bony union of the fracture will be obtained. It is superfluous to remark that it is not applicable in all cases of fracture of the femoral neck, and is positively contraindicated in cases of extreme obesity and debility, and in patients suffering from concomitant diseases which in themselves would lead to a fatal termination.

#### CONCLUSIONS.

1. From a scientific, prognostic and practical standpoint it is not necessary to make a distinction between intra- and extra-capsular fractures of the neck of the femur.
2. An impacted fracture of the neck of the femur will unite by bony union, provided the impaction is not disturbed and is maintained by appropriate treatment for a sufficient length of time for the fragments to become united by callus.
3. Impacted fractures of the neck of the femur should be treated by a fixation dressing consisting of a plaster-of-Paris case, including the fractured limb, the pelvis and the opposite limb as far as the knee, in which a splint should be incorporated by which lateral pressure can be secured in the direction of the axis of the broken femoral neck.
4. Unimpacted fractures of the neck of the femur, both intra- and extra-capsular, should be treated by immediate reduction and permanent fixation, so as to place the fragments in the same favorable condition during the process of repair as in impacted fractures.
5. Reduction is effected most readily by auto-extension and traction upon the fractured limb with the patient in the erect position, resting his weight upon the sound limb.
6. The fixation dressing should not be removed and the lateral pressure should not be discontinued for from ten to twelve weeks, the shortest space of time required for bony union to take place.
7. Patients who have sustained a fracture of the neck of the femur should not be allowed to use the fractured limb earlier than four to six months after the accident, for fear of establishing a pseudo-arthrosis at the seat of fracture.
8. The functional result is greatly improved by passive motion, massage, and the use of the faradic current.

**EUCALYPTOL IN HEADACHE.**—Dr. M. J. Lewis states, in the *Medical News*, that eucalyptol, in doses of 5 grs., six times daily, is useful in headaches, particularly those of a congestive character.

## AN INTRODUCTION TO THE STUDY OF PNEUMONIC FEVER.

BY EDWARD F. WELLS, M.D.

EIGHTH PAPER.

### CAUSATION: PREDISPOSING INFLUENCES.

(Concluded from page 53.)

Cold<sup>1</sup> has long been recognized as one of the most energetic of the predisposing causes of pneumonic fever, although the proposition has been denied by some.<sup>2</sup> I have myself no doubt regarding the predisposing influence of exposure to cold and wet in the causation of the disease, and it is to this I attribute the preponderance of persons attacked whose habits and occupations lead to such exposure.

It was the impression of Laennec<sup>3</sup> that cold, as a cause of pneumonic fever, was much less active when it temporarily followed excessive heat.

Thus "the Russian who rolls himself in the snow after coming out of the hot bath, or the baker who goes from his heated oven, almost naked, into an atmosphere below zero, is not liable to attacks of this disease."

I may add that I have seen iron and lead smelters, working in a superheated atmosphere, plunge, when heated and perspiring, into cold water, and they claim to be not more liable than others to attacks of this malady.

Exposure to cold is especially apt to be followed by pneumonic fever if the subject is depressed by

hardships, want, despair, hunger debility, intoxication, etc. There are very few physicians who have not met with the disease in patients who had been exposed to cold after a debauch.

My experience has furnished a number of instances in which unusual exposure to cold and wet has been followed by an attack of pneumonic fever.

Many years ago, whilst as yet an undergraduate, I spent a few days in a small village in which was progressing a religious revival under the auspices of ministers who deemed baptism by immersion a necessary prerequisite for admission into the church. The weather was very cold and ice of several inches' thickness covered all the streams, nevertheless many embraced religion and were baptized, holes having been cut in the ice for that purpose. After the ceremony the hapless victims stood about, in their dripping and freezing garments, for a considerable time previous to their departure for their homes, which lay, in some instances, at quite a long distance. Being a stranger in the community, and having preserved no notes, I am unable to state either the number of persons immersed or the proportion subsequently attacked with pneumonic fever; suffice it to say that the number of those who sickened was so great as to be a matter of common mention in the community and to lead to the adjournment of the meetings until the weather should have become warmer.

In the summer of 1880 a farmer was exposed, whilst overheated and perspiring, to a shower of cold rain and hail. He felt chilly at once, became drowsy, and a few hours later had a profound chill followed by pneumonic fever.

Another man lay for several hours upon the wet and cold ground and was promptly attacked by the same disease.

Instances similar to these might be multiplied from my own records and from the published observations of others.<sup>4</sup>

Hertz<sup>5</sup> considers the drinking of cold fluids at a time when the body is very warm a fruitful source of pulmonary congestions and inflammations, and I have met with several cases which seem to uphold this view.<sup>6</sup> Cold baths, under like circumstances, are accompanied by similar dangers.<sup>7</sup>

A rheumatic patient, with high temperature, was treated by immersion in a cold bath. Pneumonic fever developed at once.<sup>8</sup>

A girl was given three cold baths on the twenty-first day of an attack of typhoid fever. Fatal pneumonic fever developed during the night.<sup>9</sup>

A manufacturer, aged 40, ill with typhoid fever,

was given a cold wet pack of two hours' duration, and was immediately attacked by pneumonic fever.<sup>10</sup>

The loss to the army of Alexander the Great, after their plunge into the river Oxus while the men were thirsty, fatigued and perspiring after a march of forty-six miles across the scorching sands of the desert, was greater than from any of its battles.<sup>11</sup>

Although every writer<sup>12</sup> upon pneumonic fever is sure to mention cold as one of the predisposing (or active) causes of the disease, yet few have essayed to explain its action. The first effect of refrigeration upon the respiratory mucous membrane is to greatly contract the blood-vessels—rendering the surface pale and causing a sensation as if the lungs were torn asunder. This contraction is only temporary, the vessels gradually regaining their normal dimensions, and finally becoming greatly dilated, the color of the mucosa passing through all the shades of red, from pink to purple. The normal bronchial secretion is greatly diminished or suppressed with the contraction of the capillaries, but as these dilate it is restored and finally becomes excessive.<sup>13</sup> How much of this effect is due to refrigerating shock and how much to the abstraction of moisture from, and the deposition of chloride of sodium upon, the walls of the air-cells and minute bronchi is not definitely known. We know that the air of a zero temperature is very dry as it enters the lungs, containing only  $\frac{1}{2}$  grain of aqueous vapor to the cubic foot, whilst the expired air from the lungs, at a temperature of 98° F., is nearly or quite saturated with moisture and contains about 18½ grains of vapor of water—18 of which have been abstracted from the mucous surfaces with which it has come in contact.<sup>14</sup> This moisture is necessarily taken from the blood, and as it leaves the circulation holds in solution certain salts, especially sodium chloride, which are non-volatile and are left behind to irritate the mucous surfaces<sup>15</sup> or afford a pabulum for the growth of infective germs.

In regard to the influence of fogs and cold damp air in the production of the malady, it has been suggested that the lungs may be greatly chilled by the abstraction of the heat necessary to convert into vapor the minute particles of water contained in such an atmosphere.

There is a very close connection between night air and pneumonic fever, as is shown by the numbers of cases following exposure to its influences, and the vast majority of instances in which the attack commences during the hours of the night. The preference which this disease shows toward attacking its victims at night has led some observers to attribute to ozone, which is then present

in its maximum proportion, a causative relation to it.<sup>16</sup>

#### EXCITING CAUSE.

Formerly, in a large proportion of cases,<sup>17</sup> the attack could not be referred to any obvious cause, and from this circumstance pneumonic fever is often said to be of spontaneous origin.<sup>18</sup> That this conclusion is erroneous requires no argument. That there can be no effect without an adequate cause is an axiom of universal applicability, and it is no more reasonable to adopt the *de novo* origin of diseases, than to acknowledge the same doctrine of the origin of life or of matter. The term, unless used in a very restricted sense, should be expunged from medical writings. Not only must a given and unique effect proceed from an adequate cause, but such cause must be specific in its nature.

In the case of pneumonic fever we have a series of phenomena which, within certain limits, are unvarying, and which necessarily require for their production a single cause; of varying potency, infectious<sup>19</sup> certainly and possibly contagious,<sup>20</sup> but always unchangeable in its nature. This specific *materies morbi* may be actively destructive, or it may be an agent acting by its mere presence—catalysis—and much research has been expended in the endeavor to discover and isolate it. To-day it is generally acknowledged that the poison<sup>21</sup> must be a microscopic vegetable parasite. The acceptance of this proposition does not necessarily require the demonstration of the infectious material, for in this instance, as in so many others in nature, its existence is manifested and proven by its effects, both objective and subjective.

From the fact that pneumonic fever is ubiquitous we may infer that its essential cause is ever present<sup>22</sup> in the atmosphere we breathe, and necessarily in the lungs, but that its onslaughts are successfully repelled, until a time when, through a variety of circumstances, the system can no

longer cope with the enemy and capitulates—a victim. This ready susceptibility of the system may follow some marked change in the subject or his surroundings, *e. g.*, becoming chilled from facing an east wind, or the conditions may not attract attention.

With the entrance into the system of this exciting cause there usually arises in some portion of the lungs, and possibly in some other organs,<sup>23</sup> an irritation which attracts an increased blood supply to the part and causes the exudation into the alveoli and connective tissue of certain constituents of the blood. The entrance of these germs into the system is not always and of necessity followed by an attack of the disease. It has been shown that when certain microorganisms enter the systemic circulation they are immediately surrounded and destroyed<sup>24</sup> and the debris is quickly extruded from the economy by the excretory organs. It is probable that this destructive digestion is favored by certain conditions of both the leucocytes and disease germs.<sup>25</sup>

Various living vegetable formations are found in the exudation which fills the alveoli, in the secretions from the bronchial mucous membrane, in the substance of the inflamed tissues and in other parts of the body. That these organisms, although microscopic in size, have a very definite and intimate relationship to the pneumonic process is certain, and by a majority of pathologists<sup>26</sup> they are recognized as the *causa vera* of the disease, whilst others consider them only the scavengers of the malady, and yet another small contingent<sup>27</sup> think their presence accidental and in no wise essential.

<sup>21</sup> I here use the word "poison" in its broadest sense.

<sup>22</sup> In greater or less quantity, in various stages of development and of variable potentiality.

Of these various organisms the one simultaneously discovered by Talamon and Friedländer, and known by the name of the pneumococcus, has attracted the most attention. It is an elliptical micrococcus, in length three times its thickness, found singly, in chains, spread out in a film or grouped in masses. It is surrounded by a capsule which does not stain<sup>24</sup> readily, and which disappears during cultivation, but reappears again when inoculated in an animal. It grows readily on gelatine at ordinary temperatures without liquefying the gelatine. When the inoculations in the gelatine have been made by a needle and to a considerable depth the resulting growth assumes a nail-shape, with an elevated and spreading head.

Originally Friedländer claimed that the peculiar mucinous capsule was the distinctive portion of the organism, but this has been denied by others, who contend that the encapsulated appearance witnessed by Friedländer was due to his method of preparation. Talamon made no mention of it in his original paper, and Friedländer himself, before his death, acknowledged that the capsule was not an important part.

Repeated cultivation changes its form so that it resembles a bacillus. Its vitality is destroyed by a temperature of 136.4° F.<sup>25</sup> It will not grow in a medium impregnated with the bacillus fluorescens putridus or its products, but the reverse does not hold good.<sup>26</sup>

They are most abundant in the exudation matter filling the alveoli and in the bronchial secretions, but may also be found in the interstitial tissue, lymphatics, pleura, brain, kidneys and other organs.<sup>1</sup>

Other microorganisms may, because of their near resemblance, be mistaken for the pneumococcus. This is true of the micrococcus of erysipelas, the bacillus of whooping-cough,<sup>27</sup> the micrococcus of cerebro-spinal meningitis,<sup>28</sup> and one of the micrococci usually found in the buccal cavity.<sup>29</sup>

July 1885, p. 12. Salvioni, Arch. le Scienze Med., 1884, Vol. VIII, p. 127. Purjesz, Wiener med. Wochenschr., 1884, S. 43.

<sup>24</sup> Staining fluid. Alcohol, 50; distilled water, 1.5; acetic acid, 10; sol. gentian violet, q.s. Immerse the specimen for 24 hours. Bleach in solution of acetic acid—0.1 per cent—for one or two minutes. Dehydrate with alcohol and clear up with oil of cloves.

<sup>28</sup> Smith, N. Y. Med. Rec., May 14, 1887, p. 543.

<sup>29</sup> Pasteur, Compt. Rend. Acad. de Sci., 1881, T. xcii, p. 150. Klein, Microorganisms and Disease, London, 1885; Claxton, op. cit. Fränkel, Berliner klin. Wochenschr., 1884, S. 271. Sternberg, Am. Jour. Med. Sci., July, 1885, p. 169. Salvioni, op. cit.

The micrococcus of Friedländer<sup>30</sup> and Talamon<sup>31</sup> through a number of different kinds of animals? has been isolated by repeated cultivations and various animals, such as dogs, mice, rabbits, etc., have been inoculated with the pure cultures, with the result of inducing a pneumonic inflammation which is regarded as being that of veritable pneumonic fever,<sup>32</sup> and identical with that caused by inoculating pneumonic sputum and exudation matter. Whether these toxic effects are due to the direct action of the microorganisms or to the noxious and decomposed elements—ptomaines—which they produce is, as yet, not certainly known.<sup>33</sup>

Other microorganisms are found in the inflamed tissues of pneumonic fever, and some of these have been presumed to be the cause by their discoveries. Thus so long ago as 1877 Klebs<sup>34</sup> described a microbe—the monas pulmonale—which he considered the essential element in the causation of the disease, and his observations were later confirmed by Eberth<sup>35</sup> and Koch.<sup>36</sup>

Fränkel<sup>37</sup> and Talamon<sup>38</sup> describe a microbe which is lanceolate, with a capsule which disappears by cultivation, and which requires for its development a temperature somewhat above that of ordinary rooms. It is not certain that the microbes described by Friedländer, Fränkel and Talamon are distinct organisms.

Microorganisms peculiar to other diseases may be found, incidentally, in cases of pneumonic fever.<sup>39</sup>

These facts very naturally lead up to the question of the contagiousness of pneumonic fever. That there is a contagious element in the causation of this disease has been affirmed for a long time, although the fact has not been demonstrated.

If the occurrence of multiple cases amongst people who commingle together can be accepted as proof positive of contagion, it would be easy and quite convenient to answer this question in the affirmative. Under such circumstances, however, it has not yet been proven that the patients have not been exposed to a common cause, as owing to the universal presence of the disease, is most probable. To be sure there are numerous instances on record where, after assiduous attendance upon pneumonic patients, the nurse has been attacked by the same disease.

Blythe<sup>40</sup> reports two such examples: "A farmer at Bow, North Devon, was affected with acute

<sup>40</sup> London Lancet, 1875.

pneumonia, and was nursed during his illness by his niece. His niece became affected by the same disease and carried it to her husband. In another case, an old man, affected with pneumonia, reposed on an affectionate relative's breast during a great part of his fatal illness. The relative was very shortly affected by the same ailment."

Wyman<sup>42</sup> relates the history of a woman who died from pneumonic fever contracted whilst nursing her 9-year-old son who was ill with the same disease.

Daly<sup>43</sup> cites the case of a man who nursed his wife during a fatal attack of pneumonic fever, and himself succumbed to the same malady a week later.

Coulthard<sup>44</sup> reports the case of a large fleshy woman of 73 years, who died from pneumonia fever after four days' illness. Two days after her death her husband, of the same age, was also taken with the same disease and also died in four days. In both the right side was affected.

To these I might add several cases coming under my immediate observation, but will give only one: A gentleman, *æt.* 69, whom I had previously treated three times for pneumonic fever, died in his fourth attack. His wife, a large fleshy woman, *æt.* 79, who nursed him, also took the disease and died. They expired within forty minutes of each other—he on the ninth, and she on the fifth day of illness. The husband seemed in a fair way of recovering until he was informed that his wife would probably die, after which his courage and desire for life forsook him and he died forty minutes before her.<sup>45</sup>

In discussing this subject the limit to the meaning to be attached to the term contagion should be clearly understood. For a plausible explanation of the cases above detailed, we must acknowledge that they did not arise from accidental or common causes, but that there were present influences which acted upon the pneumonic poison in such a manner as to render it especially abundant or virulent, or that some local influences caused the patients to be peculiarly susceptible to the morbid agent, or a combination of both. Now if we employ the term contagion in its broad and original sense these cases would all be contagious, but if we limit our meaning of the word, as is now usual, to infection by a materies morbi which has been first passed through and elaborated in the system of some other patient laboring under the same malady, the conclusion

that pneumonic fever is a contagious disease is open to so much doubt that we must await further and more conclusive evidence before it can be accepted.

## MEDICAL PROGRESS.

ON THE INFLUENCE OF ANILINE AND OF THE TOLUIDINES ON THE RESPIRATORY CAPACITY OF THE BLOOD, AND ON THE TEMPERATURE.—In an article in *C. R. Soc. de Biologie*, Jan. 5, 1889, p. 10, E. WERTHEIMER and E. MEYER publish the results of experiments which show that chloride of aniline and of toluidine injected into the veins of a dog (30 centigr. per kilo. animal) cause within a few minutes an abundant transformation of hæmoglobin into methæmoglobin (proven spectroscopically). Also in vitro methæmoglobin originates very rapidly in the blood after introducing aniline or toluidine. These substances produce in the dog a moderate decrease of carbonic acid in the blood and considerable decrease of oxygen. The latter is for aniline (7.3 instead of 23.1 vol. per cent.), and for metatoluidine (6.8 instead of 20.4 per cent. o), much more considerable than for paratoluidine (13.5 instead of 23.1 per cent. o), or for orthotoluidine (15.1 instead of 24.2 per cent. o). Also the decrease of temperature effected is much greater for the two former substances (from 39° down to 32° and 30° within from five to six hours) than for para- and orthotoluidine (from 39° down to 37° or 36°).

The authors mention also the experiments of Jaffé and Hilger (*Zeitsch. f. Physiol. Chemie*, 1888), which showed a strong temperature lowering effect in metacetotoluidine, whilst para- and orthoacetotoluidine do not influence the temperature.—*Centralblatt für Physiologie*, No. 3, 1889.

ON THE TREATMENT OF HYDROCELE.—A. E. HIND, F.R.C.S., in the *Lancet* says: The treatment of hydrocele of the testis by injection of solution of perchloride of mercury was discussed, I believe, in the medical journals some years ago, but has not yet received the attention it deserves. In my hands it has always given complete satisfaction, but my cases have only been a limited number. I use a solution three times the strength of liquor hydrag. perchlor., and first draw off the hydrocele fluid and then wash out the cavity with the perchloride solution and draw off any remaining fluid. The last case on which I operated was an old double hydrocele with thick walls. The result was quite satisfactory. The injection does not cause pain, and is not followed by inflammation. In these respects it is superior to iodine. Its action depends on its power of forming an insoluble albuminate of mercury, by which the walls of the cavity are glued together.

<sup>42</sup> Boston Med. and Surg. Jour., Dec. 15, 1881, p. 569.

<sup>43</sup> Op. cit. p. 524.

<sup>44</sup> Cincinnati Lancet and Clinic, April 14, 1883, p. 353.

<sup>45</sup> For further information consult Gairdner, London Lancet, 1887, Vol. II, p. 247; Smith, N. Y. Med. Rec., Feb. 21, 1885, p. 208; Neal, London Med. Rec., Jan. 15, 1882, p. 14; Martin, Trans. Acad. Med. Ireland, Vol. 19, 1886; Chomel, Pneumonie, 1887, 5<sup>e</sup> édit., Cin. Lancet and Clinic, Oct. 28, 1882, p. 421; Kühn, Arch. f. klin. Med., Bd. xlii, Heft 4; Rosse, Cruise of the Corwin, Washington, 1883; Sturges, Nat. Hist. of Pneumonia, London, 1876; Ozanam, Hist. Méd. des Mal. Epidém., Paris, 1817, T. I, p. 76; Hecker, Epidemics of the Middle Ages, London, 1844, p. 29; Bryson, London Lancet, N. Y., 1864, Vol. I, p. 198; Cullen, Prac. Phys., Phila., 1742, Vol. I, p. 182; Juergensen, Ziemssen's Handb., Bd. v, S. 56.

As far as my experience goes, there is no danger of mercurial poisoning. The albuminate is fairly insoluble, and a large amount of mercury is not required. I have tried this treatment with success in a case of infantile hydrocele, after tapping had failed. Iodine causes pain when used, and often much pain afterwards by setting up more inflammation than is required to cure. Iodine also is not always efficacious, and may be followed by abscess. I believe perchloride is sure in its action, and its use does not necessitate rest in bed afterwards. I should like to know if the experience of others who may have used it coincides with mine. Have any ill results been known to follow? Has it ever been known to fail? What is the weakest solution that is effective?

ON THE TREATMENT OF VARIOLA AND OF VARIOLOID WITH COCAINE.—DR. ORY reports in the *Rev. gén. de clin. et de Thér.*, No. 9, that in a case of severe confluent variola improvement ensued and the eruption began to disappear immediately after the patient had taken more than ten pills of 0.002 gr. of cocaine each in one night. After a few days 10 drops of a 5 per cent. solution of cocaine muriate was given four times a day, and the patient was well inside of ten days. In another case a cure of varioloid was effected under the cocaine treatment in five days after the appearance of the pustules. A third case of acute hæmorrhagic varioloid got well without scars under the cocaine treatment within five days. Also in two children (8 drops of a 1 per cent. solution each four times a day) a cure of varioloid ensued under the same therapy in five and six days. As the blisters dried up immediately after the use of cocaine in all cases it could not be determined with certainty whether, in one case or another, the disease was not variola. Cocaine neutralizing the variola virus in the infected organism so rapidly, Ory is of the opinion that it is capable also of preventing its development in the healthy organism, and advises its use as a preventive for those surrounding variola patients.—*Wiener Medicinische Wochenschrift*, No. 22, 1889.

THE DIAGNOSIS OF PANCREATIC DISEASE.—From a careful examination of a case which was under Gerhardt's care at the Berlin Charité von Ackeren endeavors to assign a certain diagnostic importance to the presence of undecomposed carbohydrates in the urine of cases suffering from disease of the pancreas. The patient was a man 49 years of age, admitted suffering from vomiting, constipation and emaciation. To the right of the umbilicus there was palpable a painful irregular tumor which moved to the right when the stomach was full. The emaciation progressed, although the size of the tumor scarcely increased; œdema of the legs and ultimately ascites and hydrothorax

set in, and he died five months after admission. At the necropsy there was found in the pyloric region an ulcerated carcinoma with secondary growths in the retro-peritoneal glands. Two such nodes were present in the pancreas—one in the tail and a larger one in the head of the gland. Two or three weeks before death the urine, which had hitherto been normal, increased in quantity, notwithstanding the œdema, and the specific gravity went up to 1028 and 1030. Fehling's solution showed reduction only some time after heating, while the nitrate of bismuth solution turned black after some minutes' boiling. Polarized light was rotated to the right, and the fermentation test gave a positive result. The application of other tests showed these reactions as due to the presence of maltose and a closely allied carbohydrate. Indican was present in abundance, and there was no biliary pigment. The motions, although repeatedly examined, never showed any fat, but, on the other hand, there were numerous striped muscular fibres. As these symptoms were added to those of cancer of the stomach only two or three weeks before death, they probably coincided with the occurrence of secondary growths in the pancreas. The presence of striped muscular fibres in the feces was of great importance, as they have been found in nearly all those cases, although here, as shown by the constipation which existed, they could not be looked upon as due to a rapid passage through the intestine. Both this symptom and the absence of indican from the urine have been attributed to the failure of trypsin. In a case recorded by Gerhardt, where the enlarged head of the pancreas had led to intestinal obstruction, indican was absent, and that observer sought to invest it with some diagnostic significance; but it may be explained by albuminous matter not entering the intestine, as it has been shown that indican disappears entirely by the third day in cases of inanition. In this case it was present in abundance. With regard to the presence of fat in the feces, F. Müller has shown that when this occurs the case is always complicated by other conditions, especially jaundice. Here no biliary pigment appeared in the urine, nor was there any fat in the motions. According to v. Mering, the pancreas possesses the most powerful diastatic ferment; and it is probable that it is the pancreatic secretion alone which converts the maltose, derived from the carbohydrates of the food, into grape sugar. As carbohydrates do not appear in the motions, the only symptom pointing to disturbance of this process is the excretion of sugar in the urine, and in this connection it is interesting to recall the fact, long ago observed by Frerichs, that in diabetes mellitus the pancreas is frequently found much atrophied. (*Berlin. klin. Wochenschrift*, No. 14, 1889.)—*The Practitioner*, June, 1889.

Journal of the American Medical Association  
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE.....\$5.00  
SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
NO. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, AUGUST 3, 1889.

AMERICAN GYNECOLOGY.

*The Provincial Medical Journal* of England, in an editorial relating to the British Gynecological Society, pays a very high and well deserved compliment to the Society in question, and incidentally to American gynecology and dentistry. "We write with regret," says the editor, "that the Americans are ahead of us in dentistry and in gynecology. The reason is that gynecology was separated from obstetrics, and its study put on a proper basis. Excellent handbooks, as those of Thompson, Mundé, Goodell, have been published and are to be found in every practitioner's library in the States. The Americans took up the study with all the energy of a young people, and we are simply following in their wake, and attempting to interest general practitioners in a branch of practice which is the most important one to them. There is always a little difficulty in launching out a new society. Even in the practice of medicine there are jealousies, but the British Gynecological Society had even less difficulty than was anticipated. It evidently met a want; hence its hundreds of members; hence the success of its meetings and its transactions. Opposition and competition are excellent things; they stimulate to action; and the best thing for the British Gynecological Society would be personal antagonism, as we feel sure it would stir up those who are interested in it to make it a still greater success."

*The Provincial Medical Journal* evidently has considerable fighting blood in its veins; but if inclined to be aggressive it is certainly just and candid, both in regard to the British Gynecologi-

cal Society and to American gynecology and dentistry.

We Americans are certainly very much interested in the British Gynecological Society, for it has ever shown since its foundation an amount of enterprise that is really quite American! An outgrowth of the Obstetrical Society of London, it had its beginning in 1885, since when the accessions to its membership have been extremely rapid, while the character of its work has been the very best. By the Obstetrical Society it was regarded, at first, as simply a little rabble of fanatics blindly running after their leader, Tait. Three years ago an American in London was informed, by one of the most prominent obstetricians of England, that he could not possibly promote his interests either in England or in America by joining such a society as this one. To-day the British Gynecological Society has a large number of members in this country who take a very cordial interest in the work being done by the Society, many of whose home members, such as Tait, Bantock and Barnes, are well known by us not only from their published works, but from visits made us. We are little concerned in the rivalry between Sir Spencer Wells and Mr. Tait. Even if it be true that Tait's eminence made easy the establishment of a new society in which Americans at once took a great interest, we find no evidence of weak idolatry in the members. The Obstetrical Society decries its rival "because its members remove too many ovaries." After all, each one will have to decide such matters for himself.

We admire Wells and we admire Tait, and we do not believe that the former is the Obstetrical Society, or the latter the Gynecological Society. Each has had a rich experience which we who are interested in operative gynecology will do well to carefully study. Meanwhile we find that the British Gynecological Society is doing more to make its work known abroad than is any other special society in England.

HEALTH BOARDS AND PHTHISIS.

The circular recently issued by the Health Department of the City of New York, in relation to the prevention of tubercular consumption, is undoubtedly founded upon the most advanced laboratory investigations of the life history of the bacillus which is supposed, in the present state of

our knowledge, to constitute the "contagium vivum" of this disease: but it is hardly characterized by a sufficient degree of practical applicability to warrant the hope of an immediate abolition of infection. Granting the postulate that the "living germs" in the sputa of consumptives, expectorated "on the street, floors, carpets, handkerchiefs, etc.," may, after drying, "float in the air as dust," and admitting the germicidal efficacy, even in a highly albuminous medium, of mercuric chloride, it is still difficult to understand how the prophylactic directions of the circular are to be generally carried out. In the population of New York there are probably more than twenty thousand consumptive people daily frequenting public places, and expectorating their "enormous numbers" of bacilli on the sidewalks, in cars and other conveyances, in lecture rooms, theatres, hotels, and even churches. The parks naturally possess a peculiar attraction for them, and an excursion-boat commonly bears more than its statistically normal share of them. The circular wisely ordains that such persons should not be permitted to spit on anything which cannot be immediately disinfected, and adds: "The spittle of persons suspected to have consumption should be caught in earthen or glass dishes containing the following solution: corrosive sublimate 1 part, water 1,000 parts." But how is this to be effected? Shall we have in the future City of Health an army of emissaries from the Department closely watching the footsteps of each "suspicious wayfarer, and thrusting a regulation glass dish under his nose whenever he coughs? Or will there be a special bureau of auscultation and percussion to verify the suspicious cases and isolate them in an aquarium of bichloride solution?

Where the suspicious stage is past, and the certainly consumptive patient is confined to the house, it is prescribed that his rooms should have "as little furniture as possible," and that "the use of carpets, rugs, etc., ought always to be avoided." The abstract advisability of depriving a mother or wife whose days are numbered, and who is to be scientifically considered only as a focus of infection, of all accustomed comforts may commend itself forcibly to the strictly medical mind, but the strangely sentimental prejudices of the public at large will, we fear, prevent the adoption of this rule by perhaps the

majority of those who can afford the prescribed luxuries.

The recommendation to "catch the bowel discharges of consumptive patients" in vessels containing the same solution advised for the sputa is not likely to be observed among the poorer and more ignorant classes, whose overcrowded tenements enhance the proclivity to infection; and in view of the common carelessness of such folk, it may be questioned if the domiciliary storage of corrosive sublimate may not present some counteracting disadvantages, and whether it be better for their unkempt offspring to be poisoned in infancy or to die of phthisis at a more advanced age.

Other rules are given, touching the nursing of children by mothers suspected of consumption, the washing of a patient's clothing, the marriage of "suspected" persons, and divers more or less relevant minutiae of antiseptic, the theoretical propriety of which must be apparent to the meanest capacity, but the enforcement of which is problematical. For, be it remembered, this circular is not addressed to physicians, who alone are competent to appreciate the importance of its suggestions, and who may usually be trusted to take intelligent precautions as far as circumstances will permit; but is spread broadcast among the populace, who are neither educated to accept scientific conclusions nor likely to recognize the existence of tuberculosis until it has reached its final stage.

#### WITH RIGHT INTENT.

With a politician at the head of the Health Department of New York City, it is not surprising that such a bulletin should emanate from such a source. That in its application it is impracticable, we have already shown. Indeed it is easy to assume the rôle of objective and even of destructive criticism when difficult problems are involved, and to demonstrate the errors involved, but it is another thing to point out with unerring certainty the better plans and the methods to success.

While criticising its methods, THE JOURNAL desires to emphasize its approval of the purpose of this municipal legislation. Imperfect as its work may be it is nevertheless expressive of *the right intent*.

A great fact underlies this action which is of great importance to the citizen and to the State.

It involves this fact, that municipalities are charged with the surveillance of the health of its citizens. If so, it follows that when by any means the general health is imperilled, legislation should come to its rescue, and that as life is paramount to property, by so much the more should commercial interests and personal convenience yield to such restrictions as may be needful for life-protection. In emergencies absolute quarantine is the logical sequence of such legislation.

This brings us to the purpose of this article. The public mind is becoming more and more enlightened with reference to the nature of diseases. It is more and more apparent that while many affections may not be subject to control, on the other hand there is a vast amount of preventable disease, and the conclusion is legitimate that when prevention is possible, prevalence is evidence of criminal neglect. Naturally the public turns to the medical profession for the solution of those questions in which human health is involved. If we assume the responsibilities incident to the criticism of imperfect methods, we should be prepared to indicate those that are better. The province of the medical profession at the present hour is not only to deal with those that are sick, but with those that are well. And by so much more as a man is valuable to the State in health than in disease by so much the State is interested in preventive medicine. It has need, then, to be informed as to which are, and which are not preventable diseases. It needs to be correctly informed as to what may be done legitimately, and also of the difficulties which lie in the way of controlling contagious diseases.

The answers to these questions involve a vast amount of painstaking investigation and perhaps the work of years. But only by such investigation and by such patient observations can these answers be reached. Only upon knowledge thus obtained can intelligent and satisfactory legislation be based. If in their work medical men shall come to correct conclusions the honors and the benefits which shall inure to such labors will be beyond measure. If, on the other hand, premature conclusions shall be involved with serious errors, in practical application these errors will surely become apparent, and in proportion to their gravity will be the severity of criticism which the medical profession must endure.

The question involved is this: Can the profes-

sion so wisely guide an intelligent public as to assure an abiding loyalty, or shall it fail of its true mission, and provoke infidelity to the fundamental facts of sanitary science? If we are destructive in criticism, let us be also constructive of the best methods of promoting the public health, and let the necessities for correct conclusions stimulate men that are equal to the demand to at once and continuously put forth the needed effort.

#### THE RESIGNATION OF DR. DE WOLF.

Chicago has suffered a loss by the resignation of the Commissioner of the Health Department, Dr. Oscar C. De Wolf, who, through his official services as Health Officer for the past thirteen years, has contributed so much to the well-being of its citizens, and, at the same time, has gained for himself a National reputation as a man able to successfully grapple with all the difficulties besetting such a position, political and sanitary. *The Sanitary News*, editorially referring to his resignation, says: "He has practically created the Health Department of this city. . . . He has demonstrated fully his ability to preside in this capacity by his efficient ministration in a field of so great magnitude, confronting him with so many and so great difficulties. Whatever his future labors may be, his gain will not be so great as the city's loss, but in whatever field his efforts may be directed, we trust the same measure of success may attend him. His successor, Dr. Wickersham, will find a well organized department, and we hope his labors will prove efficient, and receive the hearty support of all the citizens."

Dr. De Wolf is a member of the American Medical Association, having joined at the Chicago meeting in 1886.

#### EDITORIAL NOTES.

##### HOME.

THE AMERICAN DENTAL ASSOCIATION meets at Saratoga Springs, commencing August 6th. The prospects are said to be good for a large convention.

THE CINCINNATI FREE HOSPITAL FOR WOMEN has been organized by the election of the following officers: *Board of Trustees*, Thos. H. Egan, President; Dr. H. Longstreet Hall, Secretary;

W. H. Curnayhan, Esq., Treasurer; Dr. C. L. Armstrong, H. M. Rulison, Rev. M. C. Lockwood. *Staff*, Drs. Charles A. L. Reed, Rufus B. Hall, Surgeons; Charles E. Caldwell, Pathologist; J. A. Johnston and A. I. Carson, Assistant Surgeons. A large and influential Board of Lady Managers has also been elected.

DR. JAMES F. HARTIGAN, of Washington, an active and esteemed member of the Medical Society of the District of Columbia and the American Medical Association has been appointed to an Austrian consulate.

THE ACT REQUIRING A LICENSE TO PRACTICE MEDICINE CONSTRUED AND HELD CONSTITUTIONAL.—The opinion of the Supreme Court of this State, by Shope, J., holding that in this case the validity of the statute was involved, and the appeal was properly taken to the Supreme Court, that this proceeding is not in its nature criminal, being punishable by fine, and does not come within the spirit of the law forbidding appeals or writs of error by the people, or the twice putting in jeopardy. It is simply a civil proceeding—an action of debt to recover a penalty. That the subject of the Act is sufficiently set forth in its title; that the defendant travelling from place to place with a band of music, and collecting the people together, and vending remedies and nostrums for the cure of disease, etc., without a license, was a violation of the section under consideration of the Medical Practice Act. Although this is a short opinion, there are several important questions passed upon by the court of last resort. In construing the law relating to the practice in our police courts, this opinion will well repay a careful examination and study. This opinion is published in full in the *Chicago Legal News* of July 13.

FACULTY CHANGES.—The Faculty of the College of Physicians and Surgeons of Baltimore, held a meeting recently to fill the vacancies created by the deaths of Professors John S. Lynch and Oscar J. Coskery, and the retirement of Professor A. B. Arnold, who has removed to San Francisco. Prof. Thos. S. Latimer was transferred to the chair of principles and practice of medicine and clinical medicine; Prof. Chas. F. Bevan to the chair of principles and practice of surgery and clinical surgery; Prof. J. W. Chambers to the

chair of operative and clinical surgery, and Prof. George H. Rohé to the chair of obstetrics and hygiene. Prof. Thos. Opie will continue as professor of diseases of women and dean of the faculty. To fill vacancies created by these transfers new professors were elected as follows: Prof. Henry Sewall, of the University of Michigan, to the professorship of physiology; Dr. George J. Preston to the professorship of anatomy, with the diseases of the nervous system as a clinical branch of instruction. Dr. N. G. Keirle was elected as lecturer on legal medicine, in addition to his demonstrations in pathology; Dr. George Thomas as lecturer on diseases of the throat and chest; Dr. G. A. Liebig, Jr., of Johns Hopkins University, lecturer on medical electricity, and Dr. J. H. Branham, demonstrator of anatomy. Drs. L. F. Ankrum, Frank C. Bressler and F. G. Moyer were appointed assistant demonstrators, and Dr. R. G. Davis, prosector of anatomy. As an evidence of esteem on the part of his colleagues, Prof. Arnold was elected emeritus professor of clinical medicine on his retirement.

MILWAUKEE'S GARBAGE CONSUMER.—Sanitarians and health officers have endeavored from time to time to solve the problem of how to dispose of the accumulation of garbage in the large cities. Milwaukee has adopted a consumer known as the Merz process, and which is described by a contemporary as follows: About thirty-five tons of garbage—"good, clean garbage," free from ashes—is delivered at the works every day at this time of year. The wagons drive up an incline and unload upon the second floor, where it is immediately thrown into the dryers. The dryers are tanks about fourteen feet long and five feet in diameter, having a double cylinder—a small one inside of a larger. Between the shells, or the cylinders, is a steam space of two inches, which has a boiler pressure of eighty-five pounds on constantly. The cylinders have cast-iron heads, and a large hollow shaft running through the centre of the inner cylinder. This is also filled with steam, and revolves by means of gear wheels, keeping the contents in circulation until thoroughly dried.

The moisture is drawn off by means of a large exhaust fan through a twelve-inch pipe and forced into a spray condenser. When the material is thoroughly dried it is discharged from the dryer

into a conveyer, which deposits it into square tanks called extractors. After being sealed and made air-tight benzine is introduced into the extractors and the grease is dissolved with a solution of hot benzine. After the grease has been dissolved and washed out, the material is sold for fertilizer.

The benzine is distilled out of the grease over again and used. The grease is sold to soap and candle makers.

#### FOREIGN.

**SMALL-POX AND TUBERCULOSIS.**—At the late Congress on Tuberculosis it was stated that persons who have had small-pox are peculiarly liable to tuberculosis. M. Landouzy deprecates the employment of persons pitted with small-pox around the tuberculous wards of infirmaries and hospitals.

**WANTED, AN EDITOR.**—*The British Medical Journal* says: "‘I want a hero—an uncommon want,’ sang the poet. A still more uncommon want, one would have thought, would have been that of an editor for a medical journal. Yet from this cause the *Breslauer ärztliche Zeitschrift* came to an untimely end on June 29. It has been impossible to find ‘a commanding personality’ to supply the place of the late Professor Gscheidlen, who founded the journal and gave it the prominent place it held in German medical literature during the ten years of its existence. Those interested in prolonging the life of the defunct periodical should have sought for what they wanted in this country, where would-be medical editors grow on every bush."

Why not have crossed the Atlantic, where medical editors are more plentiful than the "would be" ones in England?

**IN ENGLAND** a London health inspector reports a number of cases of diphtheria caused by cats going from house to house and thus carrying the virus. Queen's Hospital, Birmingham, is the recipient of \$5,000 by the will of Mr. George Dawes, of Smethwick. Dr. Burroughs lauds nitro-glycerine as a quick stimulant in place of alcohol, and gives as the ordinary dose 1 drop of 1 per cent. At a recent meeting of the Royal Botanical Society Mr. R. G. Lecky described, in a very interesting paper, a new edible seaweed found on the coast of Ireland, and which, according to the author, is a nutritious, wholesome, and cheap food, so excellent in taste that it may be called a luxury.

**IN FRANCE** the students in Paris have decided to wear distinctive badges to denote the courses which they are pursuing. Dr. Gautier, while pulverizing dry discharges for the purpose of making experiments as to infection by tuberculous germs, became himself infected and died. Dr. Lancereaux, physician to the Hôpital de la Pitié, objects to the use of movable stoves, which are apt to cause carbonic acid poisoning. The Société Médicale des Hôpitaux have recognized the necessity of isolating cases of whooping cough, which the members consider far more contagious than either scarlatina or measles, and have approved the organization of small wards, containing six or eight beds, instead of the large wards which are now used.

## SOCIETY PROCEEDINGS.

### AMERICAN MEDICAL ASSOCIATION.

#### Fortieth Annual Meeting. Report of Sections.

##### *Section on Laryngology and Otology.*

##### FIRST DAY, TUESDAY, JUNE 25.

DR. W. H. DALY, of Pittsburg, Pa., delivered the Chairman's address, entitled *Marking an Era in Laryngology*. The author referred to this, the first meeting of the Association of Laryngology and Otology, as an exclusive and autonomous Section, disassociated from the Section of Ophthalmology. The laryngologists and otologists have long agreed, that to be an able practitioner in either speciality one must be well informed and competent in both of these special branches. While there is little call for the special skill of the laryngologist in treatment of the eye, we are convinced that there was no mistake in expressing the opinion eight years ago at the International Medical Congress that the laryngologist of the future must be more of a rhinologist, and the rhinologist more the surgeon than the physician. As by far the largest number of inflammatory diseases of the middle ear cannot be successfully attacked without the skill of the laryngologist and rhinologist, since the largest number of these cases begin in the naso-pharynx and are only arrested by the proper skill in treating these parts. The new relation is close, rational and common sense.

DR. JOHN MCKENZIE, of Baltimore, reported *A Case of Lymphoid Tumor Originating in the Floor of the Pyriform Sinus*, and threatening suffocation when the patient was in the recumbent

position. A clergyman, æt. 42, had never had any throat trouble, and was otherwise in perfect health. There was no assignable cause for the growth. On microscopic examination it was found to consist entirely of the lymphoid tissue of the pharynx recently described by Waldeyer and his pupils. The tumor was removed by first exciting gagging, so as to throw it as far as possible up towards the back of the tongue. It was then caught with a pair of laryngeal forceps, and with these as a guide, the large écraseur was passed over the tumor and it was rapidly cut through. The reporter remarked that growths of various kinds are occasionally found on the pillars of the fauces, glosso-epiglottic fossa, and upper pharynx; but tumors originating in the pyriform sinus are exceedingly rare, and that the growth described is unique.

DR. SOLIS-COHEN remarked that it was rather curious that this unique growth originated in the position from which some few cases of lipoma had taken origin.

DR. JONATHAN WRIGHT, of Brooklyn, N. Y., read a paper on *Nasal Bacteria in Health*. The bacterial contents of the normal nasal chambers in ten cases were examined by culture methods and by cover-glass preparations, with the result of finding the staphylococcus pyogenes in six of the ten, and only air forms in others. The function of the nose as a bacterial filter of air passing through it, was spoken of, and photographs shown of one experiment which showed mold growths on gelatin plates. As far as the limited experiments of the author of the paper went, about three-fourths or four-fifths of the total number of the bacteria in the air find a lodging place in the nose before the tidal air reaches the lower pharynx. The paper was preliminary to more extended bacterial investigations into nasal diseases.

DR. JOHN MCKENZIE thought the solution of many points in nasal pathology by bacterial investigations would not be an event of the immediate future. The problem is an intricate one, especially in view of the constantly changing environment of the individual. The dependence of ozena on micrococci has not been determined.

DR. W. FREUDENTHAL, of New York, read a paper on *The Connection Between Chronic Diseases of the Upper Air Passages and Hernia*. In continuation of former observations the author found that in accordance with the frequency of nasal disease, hernia are found: In the United States in 50 out of every 1,000 conscripts; in France, in 22.89; in Italy, in 16.61; in Austro-Hungary, in 14.69; and in Germany in even less than 14. Furthermore, the author of the paper proves the correctness of his theory, against Dr. Schaefinger who had affirmed that facts do not sustain it. In women hernie are rarer than in men, on account of the weaker stress used in act

of hawking, clearing the throat and the like.

DR. J. H. BRYAN, of Washington, D. C., read a paper, entitled *Diagnosis and Treatment of Abscess of the Antrum of Highmore*. The author, after describing the antrum and its relations, remarked that until recent years abscess of the antrum was thought to be very rare, but that we now know that it occurs quite frequently. Of surgical affections, suppurative inflammation plays the most important part. It generally occurs after the second dentition. Among causes are traumatism, exanthemate, syphilis, extension from the nose of inflammation of its lining membrane, extension from inflammation caused by carious teeth. Authors differ as to the relative frequency of these causes. The author regards sero-mucus accumulation or hydropsantri as the result of nasal disease, but muco-purulent as arising from carious teeth. The close relation of roots of the second molar teeth with the antrum affords ready communication of disease from them. Symptoms vary in different cases. Sometimes there is distention of the walls of the superior maxilla and swelling of the cheek, etc., tenderness on pressure, a springing deviation to the finger on pressure over the distended cavity. A narrowing of the field of vision by pressure on the floor of the orbit, is regarded by Ziem as diagnostic in favor of disease of the ethmoid cells. In some cases there is a discharge of fetid pus from the nose. Pus from the nose may be due to foreign bodies, disease of bone, secretion of pus from the antrum or from the frontal sinus. Otherwise suppurative inflammation of the nose is extremely rare. The author then pointed out the indication which should guide in distinguishing among these possible sources a given case.

A great deal has been written recently as to treatment. The author noted the tendency to return, after a century, to Hunter's method of opening through the nose, instead of through the mouth. Cooper's method through the alveolar process has been in greatest favor. Extraction of teeth may be necessary, and if sound ones this is an objection to the method, and this is the case with which foreign substance and bacteria from the mouth may penetrate through the opening. Its advantages are easy drainage and washing out with antiseptics. Bertrand opened through the hard palate. Hartman has revived Hunter's method. This does not afford easy means for evacuating thick pus and for washing out, etc. Stoerk claims several cures by this method. The author thinks its disadvantages will prevent its general acceptance.

Miculicz advises opening where the lateral wall of the nose is thin, and uses a special double cutting knife, attached to the handle at blunt angle. Local anesthesia by cocaine is sufficient. By this opening the floor of the cavity is well drained and easily syringed out, and there is little danger of

foreign bodies gaining entrance as when the opening is through the mouth. Local treatment is important—washing out with mild disinfectants. The best for fetor is permanganate of potash.

Some cases will require where the inflammation is obstinate, the author recommends, the use of peroxide of hydrogen; or better, glycozone—a mixture of glycerine and peroxide of hydrogen. It destroys the septic material and stimulates at once.

The author gave the history of several cases treated by himself.

Discussed by Drs. Lippincott, E. Fletcher Ingals, Daly and Boyan.

DR. JOHN O. ROE, of Rochester, N. Y., read a paper on *Glandular Hypertrophy at the Base of the Tongue*. The author remarked that in the near past this condition, which is not rare, has been overlooked for the most part. Collections of mucus and lymphoid glands aggregated in various masses in the naso-pharynx, fauces, are of the same general nature and have received the name "tonsil." The lingual tonsil is so situated as to be easily irritated by solids and fluids of different temperature and character. They are surrounded and supplied with a system of blood-vessels. By these exposures to irritation they are especially exposed and become congested, enlarged and varicose. This condition may also be due to general plethora and may indicate portal congestion, mitral disorders, or even cerebral tumors. The diagnosis is easily made by inspection on drawing the tongue forwards.

The treatment involves two measures: First, to remove the growth. This is done with a curved knife, by slicing off down to the normal level, or with a pair of scissors curved on the flat. This operation is attended with very little bleeding, the tongue heals quickly and is attended with very little soreness. The galvanic cautery may be used, either the knife cutting through the base or by transfixing with a needle. The other measure of treatment is to destroy the varicose vessels. This is best accomplished with the galvano-cautery by use of a fine point applied along the course of the vessels. Caustic is used by some, nitric, chromic acid and Vienna paste—but when a great amount of hypertrophy is present the operative measures are best.

Discussed by Drs. Solis-Cohen and Green V. Woolen.

#### SECOND DAY, JUNE 26.

The following were elected officers for the ensuing year: Dr. John O. Roe, of Rochester, N. Y., President; Dr. Frank H. Potter, of Buffalo, N. Y., Secretary.

It was voted, on motion, that the Secretary select an Associate Secretary, familiar with otological knowledge, and living at the place of meeting of the Association next year.

On motion of Dr. Solis-Cohen, it was voted

that hereafter one meeting of the Section be devoted to subjects of otological interest.

DR. D. BRYSON DELAVAN, of New York, read a paper entitled, *Adenoid Hypertrophy at the Vault of the Pharynx: its Pathology and Treatment*. The writer stated that there were two principal varieties of this disease. In one the growth was soft, friable and rich in lymphoid elements, in the other there was an excess of fibrous tissue. The first was removable with ease and with little pain, the latter was exceedingly tough and removal caused much pain. The methods of operation were alluded to and it was insisted that in the more severe cases, even in young adults, the use of anæsthesia was of the greatest importance, and that the removal should be completed, if possible, at one operation. The writer also insisted upon the great importance of the proper after-care of patients thus operated upon, and recommended that they be kept in bed until the general effects of the operation had disappeared, that they be put upon a course of tonic treatment, that the mouth-breathing habit be corrected, by special attention thereto, that deformity of the chest, if present, be remedied by proper physical exercises, and, finally, that errors of pronunciation be eradicated. The paper was illustrated by numerous instruments and by several fine colored drawings.

DR. JOSEPH A. WHITE, of Richmond, Va., then read a paper entitled, *The So-called Third Tonsil*.

The author's experience and observation led him to believe that glandular hypertrophy in the post-nasal space, however produced and however little, is an active agent in keeping up a catarrhal condition of the region and causing its extension to neighboring cavities, especially the ear. To get rid of naso-pharyngeal catarrh it was necessary to destroy hypertrophied tissue as a means to this end, and to the same end chronic follicular tonsilitis, so-called, must often be removed. We do not know the exact function of these glandular structures, but we do know that their removal is followed by no disaster. Perhaps the third tonsil plays a greater part with production of secondary disease than the faucial tonsils. This is easily understood when their relations to the blocking up of the air-passages and interference with the proper ventilation of the Eustachian tube is considered. Marked impairment of hearing is always present in these cases of soft lymphoid tissue. Besides the mulberry-like growths there may be round or conical nodules, or several knob-like outgrowths, or flat, cushion-like nares, etc. Sometimes these are soft and easily removed. Sometimes they are dense and hard. The Eustachian tubes are especially injured by tissues of the latter character, the opening being seriously dammed by their pressure. Such are more difficult to cure. Statistics are unreliable, because slight deafness

is overlooked in these cases. Careful tests will usually discover more or less deafness where these growths exist. Out of 565 cases during the past eighteen months, treated for naso-pharyngeal affections 197 had disease of the middle-ear. Of the whole number, 134 had hypertrophy of the third tonsil, of whom 62 had impaired hearing—20 per cent. Perhaps the larger proportion than reported by other observers is due to peculiar climatic influence. An interesting point in these cases is the large number of voice troubles found among them, and laryngitis, resulting from these hypertrophies in the vault of the pharynx. The vaulted space should be perfectly preserved in shape if resonance and timbre of the voice is to be preserved, as is well known from our experience with singers and others who habitually use the voice. Naso-pharyngeal troubles are always aggravated by these glandular enlargements, causing increase of secretions, etc., and this prevents the benefit of other local treatment, unless the hypertrophies are first removed. One of the serious results of the neglect to do this is anterior turbinated hypertrophy. Another is the occasional paralysis of the ala of the nose, causing serious impediment to breathing. It matters little how the growths are removed provided it be thoroughly done. Large masses are best removed with the galvano-cautery, snare, or cutting forceps. So also of the denser growths mentioned above. The use of the forceps is quite painful, even when cocaine is used. Smaller hypertrophies and smooth masses are best removed by galvano-cautery points or moxa-electrodes. The author had found his palate-retractor of great help in such work.

The paper was followed by a report of cures and exhibition of specimens.

DR. LAWRENCE TURNBULL read a paper *On the Value of Antiseptic Treatment, and Protection for the Membrana Tympani, in Perforations the Result of Otorrhœa*. He stated that it was not necessary at this time to advocate or dwell at length upon the great value, nay, absolute importance, of antiseptic surgery. Its latest triumphs and most brilliant results have been shown in brain surgery. It is not only possible to reach and drain abscesses in the tempo-sphenoidal lobe of the cerebrum, but it is considered possible to save life by opening into the cerebellar fossæ and remove pus from the neighborhood of the lateral sinus. The antiseptic treatment of chronic purulent disease of the middle ear was a natural sequence, and was soon followed by the use of boracic acid in powder and solution, and still later by the superior antiseptic agent, bi-chloride of mercury, alone or combined in solution; then by the use of antiseptic wool, and gauze, with the protecting agency of oiled silk, which protectors act as artificial membranes and prevent the entrance of diseased germs from the air.

The author of the paper then dwelt upon the

various causes preventing the cure of chronic discharge from the ear. Also the treatment of perforations of the membrana tympani by means of grafts of skin, lining membrane of the chicken egg, skin of the frog's foot, and nictitating membrane of the frog's foot.

The paper concluded by reporting a few cases in illustration of the subject.

DR. C. W. RICHARDSON, of Washington, D. C., then read a paper on *The Possible Danger of Injury to the Middle Ear Cavity by the Use of Nasal Atomizers, Illustrated by Three Cases*.

The author expressed the expectation of exciting criticism and skepticism. The object of the paper was to call attention especially to danger to the middle ear as a result of atomization of the nasal cavities by such instruments as Davidson's and Snowdon's atomizing tubes from direct pressure. The first case, that of a lady, being treated for rhinitis atrophica. During the use of the spray with Dobell's solution, pain was experienced in the ear. This was followed in a few hours by serious ear trouble, pain radiating over the side of the head and along the Eustachian tube. Effusion set in and was attended with deafness, roaring in the ear, etc., all the symptoms of acute otitis media.

The second case occurred in a gentleman who had great hoarseness and naso-pharyngitis. While using the spray the patient remarked, "Doctor, that certainly entered my ear." The spray was stopped at once. Soon after great pain set in and became almost unendurable. The pain was of a throbbing character, intensified by coughing, clearing the throat and swallowing. There was tenderness over between the mastoid and the jaw, hearing reduced R.  $\frac{2}{3}$ , L.  $\frac{1}{5}$ . Cerumen was found in R. E. It was removed, and hearing then was R.  $\frac{3}{5}$ , L.  $\frac{2}{5}$ . The membrane of right ear then showed evidences of morbid inflammation. It was a case of acute middle ear inflammation, well marked.

In case third, Dr. L. consulted the author in February, 1889, for severe pain in right ear, and was constantly annoyed by obstruction to free nasal respiration. The spray was tannic acid gr. j to 5j. This was followed, like the other cases, with acute symptoms of middle ear inflammation. Cases published by Dr. Ring in the *Medical Record* of August 11, 1888, were referred to by the author.

The author gave his explanation of the manner in which the spraying under pressure excites middle ear trouble. He declared it a common experience with himself, as he had no doubt it was with other laryngologists, that under the spray patients often express the sensation that fluid has entered the ear. The intention of the paper was not to decry the use of the atomizer, but simply to call attention to possible dangers. The author also called attention to the fact noticed by him that the use of the spray may be the direct agent in producing otitis media hypertrophica.

DR. MACKENZIE believed that fluid may enter the ear by any method of cleansing the nose, and that the danger does not pertain specially to the spray. He narrated a case of double otitis media resulting from the use of intranasal spraying. His remarks did not apply to the nasal douche.

Discussed by Drs. Wright and H. H. Curtis.

DR. J. L. THOMPSON, of Indianapolis, Ind., read a paper entitled: *Report of Cases of Dangerous Middle Ear and Mastoid Inflammation which followed Treatment of the Naso-Pharynx*, in which he gave the history of, 1, case of suppurative otitis media excited by the use of finely powdered acetate of lead in epistaxis; 2, case of otitis media with extension to mastoid following application of strong solution of nitrate of silver to the nares; 3, otitis media, following application of caustics to the nasal mucous membrane; 4, case of suppurative otitis media of five years' duration following applications to the nares; 5, case of suppurative otitis media with total loss of right drum head and greatly impaired hearing following surgical treatment of naso-pharynx. The history of twenty cases of similar nature were reported by the author at considerable length, of similar origin and of the same general character as those above cited. The author remarked in conclusion: 1, that from his experience he was convinced that inflammations from said causes are of very frequent occurrence; 2, operations should never be made nor caustics applied to the nose during acute catarrhal inflammation of the parts; 3, patients should be instructed to report immediately on the first twinge of pain in the ear after an application to the nose; 4, the operator should be prepared to leech, puncture the drum, etc., promptly as soon as indication arise, and the operation for puncturing the mastoid, when extension to it has taken place of the inflammation, should by no means cause hesitation.

Discussed by Drs. H. H. Curtis, Ingals, and Woolen.

DR. J. G. CARPENTER, of Stanford, Ky., then read a paper entitled: *Internal Ear Deafness, Illustrated*. Internal ear deafness, in many of the cases, is due to nasal disease, and that by causing the latter the former is relieved, and that nasal disease should be cured before structural lesions have taken place in the inner ear. Report two cases in which in addition to chronic naso-pharyngeal catarrh for the predisposing and acute catarrh for the exciting cause, syphilis was an important factor in one and quinine in the other. The air in the Eustachian tubes and middle ears normally being in a rarefied state, that warm rarefied air should be used for inflation of the Eustachian tubes in preference to cold air, the acute and subacute congestion and inflammation should subside, the chronic congestion of the upper air-passages reduced to a minimum before inflation of

the middle ears. In the cases reported there had been also aural catarrh and tympanic deafness before the labyrinthian deafness supervened.

DR. J. A. LIPPINCOTT, of Pittsburgh, then read a paper entitled: *A Case of Sclerosing Mastoiditis, occurring subsequently to Primary Purulent Mastoiditis Interna. Opening of Mastoid. Exposure of Dura Mater. Recovery*.

The mastoid process had been opened in Sept., 1885, in a distant city, and an abscess found, which was carefully cleansed. The wound soon healed, and the severe pain was relieved for six months, when it recurred, gradually becoming more severe until July, 1886, when the case came under Dr. Lippincott's observation. All sorts of treatment, local and constitutional, failing to afford relief, Dr. L. made a pretty considerable opening in the mastoid, in October, which unfortunately accomplished nothing. The condition of the patient now became more and more deplorable. Notwithstanding the administration of large quantities of morphia, chloral, etc., pain was never absent. The patient became emaciated and haggard. Convulsions set in and occurred frequently. Seven months after the last operation, viz., in May, 1887, at the urgent solicitation of the young lady, a second operation was made. In the effort to make the opening this time sufficiently large and deep to give relief, the dura was exposed in the anterior part of the bottom of the wound to the extent of  $\frac{1}{4}$  inch. On recovery from the anæsthesia the pain was found to have disappeared. Convalescence was rapid and uneventful, and the young lady resumed her work two months after the operation. A final examination made a few days ago reveals the same happy exemption from pain. It should be added that the chief symptom in this case was the extreme pain, there being no inflammatory appearances about the ear or the mastoid region.

DR. FRED L. CROSSFIELD, of Hartford, Conn., read a *Report of Two Cases, illustrating Epilepsy Caused by Intra-Nasal Disease*.

The first case came to my notice in 1886, and had all the appearances of some severe lesion of the lung. Emaciation, hacking cough, more severe at night, headache, night sweats, and poor appetite. Had epileptic convulsions past six years, twice a month or oftener. In connection with this condition he had marked nasal hypertrophy, both sides, with deviation of septum, left side, and exostosis in form of sharp angle, which pressed against the hypertrophied turbinated body. Marked adenoid growth of naso-pharynx, slight changes in the larynx. Epilepsy entirely disappeared when pathological condition removed. Patient now perfectly well. Second case much like the first, only slight enlargement of pharyngeal tonsil. The epileptic seizures much more frequent. This case likewise fully recovered on removal of the cause.

DR. CHARLES H. KNIGHT, of New York, read a paper on *Menthol in Laryngeal Phthisis*. Twenty cases, most of them of a severe type, treated with menthol applications, furnish the author ground for believing that this is a valuable agent in tubercular laryngitis. The drug was dissolved in fluid albolene, in the proportion of 1 drachm or  $1\frac{1}{2}$  drachm to the ounce, and applied by means of a laryngeal syringe, or in the form of spray, or with a nebulizer or vaporizer. In nearly all cases the subjective symptoms and the local appearances improved. In no case did complete healing of an ulcer take place. In this respect the author's experience does not bear out the representations of Rosenberg and others. Three propositions are offered: 1. Spontaneous cure of a tubercular ulcer of the larynx may occur. 2. A simple erosion or ulceration may be mistaken for a tubercular ulcer. 3. The best results from local treatment of the larynx may be expected in cases of incipient or limited pulmonary disease and in primary laryngeal tuberculosis.

DR. F. H. POTTER, of Buffalo, N. Y., then read a paper *On the Use of Menthol in the Upper Air Passages*, in which he reported the results obtained from its local application during the past three years. These results indicate that menthol controls superficial inflammations; that it is an analgesic and second applications can be made in increasing strength without discomfort; that it is destructive of some of the low forms of life, especially the bacillus tuberculosis, and that it is a valuable antiseptic in nasal surgery. It has an important place in the treatment of atrophic conditions. It can be used in strengths from 1 to 50 per cent., dissolved in an oil. The *Oleum Petrolina*, one of the petroleum preparations, the author considered the best for this purpose of dissolving the drug. It can be applied quickly by the cotton applicator or by means of the spray, or by vaporization. The direct method answers best in the pharynx, the spray and the vapor for the nose and larynx. Five cases of laryngeal phthisis consecutive upon disease of the lungs were also reported, in which the menthol treatment gave satisfactory results, the local diseased processes improving rapidly under its use.

DR. E. FLETCHER INGALS, of Chicago, Ill., read a paper entitled *Electrolytic Treatment of Cystic Goitre*. Various conventional methods of treatment of cystic goitre were referred to by the author, and especially that of Sir Morell Mackenzie, first published in 1872, and which is pronounced in Holmes' System of Surgery as the most efficient. It consists, as is well known, of injecting into the cyst a solution of perchloride of iron, plugging the canula of the trocar and allowing it to remain in three days, and repeating the procedure until suppuration occurs, aided by the use of poultices. The author claims that electrolysis promises more rapid cure and better re-

sults, and is attended by less danger and objectionable features. In support of this position he gave the history of two cases treated by himself.

In the first case, after the use of other methods had proved inefficient, electrolysis was employed. One pole, a needle, was introduced into the cyst, the other placed upon the tumor. By previous tappings the tumor had been found to be about one-third solid. From six to ten Leclanché cells were used for about ten minutes. This was repeated at intervals of a week three or four times, when the tumor ceased to refill and has remained cured. The solid part was unchanged and has not increased since. The second case was one which had existed for several years and had been injected with iodine and other fluids. On February 23 the tumor was found not to have diminished in size. Electrolysis was now used as in the former case. In a month from that date the cyst had ceased to refill and had been completely eradicated by electrolysis. The strength of the current in this case was graduated by the ability of the patient to bear it.

DR. HOLBROOK CURTIS, of New York, read a paper on *Anæmia and its Relation to Nasal Stenosis*. By a tabulation of cases he demonstrated that nearly all patients with stenoses were anæmic, the percentage of oxyhæmoglobin being only about one-half that of normal blood. In his experiments he had used the hæmatoscope of Hénocque, and had again tested the blood after several weeks had elapsed. The conclusions arrived at were that the increase of oxyhæmaglobin in the blood after operations on the septum is directly proportional to the relief afforded an impeded nasal respiration. This increase is constant and averages about 2 per cent. in the six weeks immediately following operations in which the stenosis is about 50 per cent., or in which the nose is doing but one-half its work. Cases should not be operated upon whose blood shows by spectrum analysis less than 6 per cent. of oxyhæmoglobin, as profound hæmorrhage is apt to occur. Records had also been kept in regard to body weight, chest measurement, and capacity of the lungs by the spirometer. These factors also exhibited improvements after operation.

#### THIRD DAY, JUNE 27.

DR. J. E. SCHADLE, of St. Paul, Minn., read a paper on *Cough in its Relations to Morbid States of the Nasal Passages*, in which he stated that the symptomatology of morbid processes seldom presents a more perplexing subject for analysis as to its primary cause, than that of cough. A chronic cough, whose persistency will not yield to ordinary methods of treatment, and whose ultimate significance is sometimes difficult to understand, is calculated as much as any other single condition to establish in the mind of the sufferer extreme anxiety. An important interest belongs to

this subject, especially in its *practical* relations to morbid states of the nasal passages. Three cases were reported in which chronic cough of long standing was cured by directing proper measures of treatment to a removal of the existing nasal disease, consisting in one, of posterior hypertrophies of the inferior turbinated bodies, one nasal stenosis, caused by deformity of the nasal septum, and one, chronic nasal catarrh. The author maintains that when cough is thus pathologically connected with morbid states of the nasal passages it is usually produced by reflex nervous influences or paresis of the vaso-motor blood-vessels of the intra-nasal mucous membrane.

DR. CHARLES DENISON, of Denver, Col., read a paper entitled *A New Mouth Gag. Together with the consideration of other possible aids to better results from Intubation of the Larynx*. The author presented a table of his intubation cases, numbering 25, with 7 recoveries. These were shown to be a severe class of cases. The author had experimented to construct a better gag than that usually employed, and exhibited four of the new varieties made. The next to the last one, made by Tiemann & Co., is intended to be held close to the left cheek of the child by the assistant, and is calculated not to get out of place during the operation. A new feature about all these gags, an idea of the author's, is to have the teeth troughs made somewhat swivel, so that they will fit any angle of the jaws, *i. e.*, any aged child. The power to open the jaws is afforded by a lever attached to a toggle-joint placed between the two sidearms of the instrument.

The last gag was simpler in construction, more compact, and gave greater power to open the mouth of a rebellious patient. In fact it cannot be resisted. A pin on one arm lies in an elliptical groove attached to a circular plate, the center of which is pivoted to the other arm of the gag. By three turns of this plate the extreme distension required in any mouth is obtained. The author had been bitten, and had other accidents, from the loosening of the original gags sold with the O'Dwyer sets of tubes. This last instrument was made by H. Rauefurs, of Denver. The great necessity for earlier intubation than he thought was customary with operators was then shown. In two successful cases when the author had intubated he had been led to avoid delay by noting that the tension of the pulse was less during expiration, showing that there was already suction of blood back into the thorax during inspiration, in other words, an aspiration because of the laryngeal constriction was taking place. The author called this an *edema* of the *air-cells*, and he was led to believe that this was the inauguration in young children of a catarrhal process in the lung periphery and bronchial tract, usually resulting in death in from twelve to forty-eight hours after intubation.

In 9 of his 18 fatal cases death came in an average of twenty-six hours after intubation, and these deaths were by the writer attributed to this aspiration *cedema*, or "aspiration pneumonia," as Dr. O'Dwyer calls it. A case in illustration was given where the author desisted from intubation because the child was evidently dead. He directed this patient, a little boy 4 years old, to be laid back upon the bed, when noticing another gasp he thought he would intubate anyway. He did so as the child lay on his back upon the bed and without the use of any gag whatever. Artificial respiration was then used and the child resuscitated. After half an hour the child drank some milk, was bright, and the household was filled with hope. However, as might be expected, the child died in twelve hours. This counted as one of his cases of "aspiration *cedema*."

Again the author introduced what he supposed might be an important consideration, with reference to the remarkable fatality from pulmonary complications, both after tracheotomy and intubation. After intubation the records thus far given show 60 to 70 per cent. of the deaths to have occurred from "extension to bronchi," etc. This cannot otherwise be explained except that damage had occurred before and at the time of operation, or else, as the writer suggested as possible, after the operation, and because of the practical abolition of the use of the larynx. He wished to ask that this latter point be investigated, and that someone competent to give the answer would state, *What is the result of this substitution of an inflexible metal tube for the delicately-organized human larynx*, especially in extreme youth, a period when most of these accidents occur? A solution of this problem might lead to the use of somewhat elastic or flexible tubes. While the question of "aspiration *cedema*" might suggest the use of the sphygmograph to determine the need of an early operation, as well as after either intubation or tracheotomy the substitution of condensed air for the inhalation of air at the ordinary pressure. The use of the pneumatic cabinet may here perhaps be most advantageously employed. Judicious experimenting by those who have cabinets might result in good.

It was claimed that only in some new way of management would this fearful mortality from lung complications after intubation be greatly lessened. The condition of sepsis does not explain it, nor does the entrance of food through the tube.

DR. D. N. RANKIN, of Alleghany, Pa., read a paper on the *Effects of Natural Gas upon the Upper Air Passages*. Natural gas was first used in Pittsburgh as a fuel in 1883. The complaints were loud and many that the heat that it produced made the air too dry for breathing and produced irritation of the throat and nose. Some ceased to use it, others moistened the air with steam from

kettles of hot water, etc. The dryness was not imaginary. It cracked furniture and joints in woodwork—pianos and other expensive furniture was ruined by opening glued joints, etc., before steam was used to moisten the air. It is of great benefit for fuel and light in manufactories and dwellings on account of its cheapness. Before it was learned how to control it explosions occurred. As now managed this rarely occurs. Natural gas is not new. It is mentioned by the ancients, "The Holy Fires of Baker." It was utilized in Germany at Collesgabe for illuminating purposes. In Pittsburgh and vicinity there are now used 600,000,000 cubic ft. daily. The author gave a chemical analysis of the gas, which disclosed its noxious properties when inhaled.

Patients usually complain first of dryness of the nose and throat, followed by free discharge of muco-purulent matter from these cavities; after which the dryness recurs, sometimes the irritation extending to the larynx and producing considerable hoarseness. Examination with reflected light shows considerable congestion in the nose and pharynx. The extreme sensibility of these parts is promptly relieved by 4 per cent. solutions of cocaine, followed by the application of vaseline to the nose and pharynx. At first gas pipes were made of too porous metal and leaked. This has now been remedied, and now those who have had the gas removed from their dwellings are having it restored.

Conclusion: Since the various improvements in managing it have come into operation the gas can be used without fear of suffocation or any deleterious effects, such as result from inhaling too dry atmosphere. Certainly it is not healthy to breathe, but since it has been taught how to use it, it is no longer breathed by those who use it.

DR. GEORGE A. RICHARDS, of New York, read a paper: *Empyema of the Frontal Sinuses*. The author reported a case of empyema of the frontal sinuses due to obstruction of the infundibulum by polypi which had existed fifteen years. The empyema had produced absorption of the lower wall of the sinus and a small tumor had appeared at the root of the nose about eight months before patient consulted. Opening made into swelling and tube passed through into nose, after about twenty polypi were taken out. After thorough cleansing thrice daily for about a month, patient recovered completely, sight improving at once, also a complete relief to a previously very marked aprosaxia and great improvement in general health, as well as in breathing and smell. Of forty-eight cases collected from literature, only fourteen cases were the result of injury, and but seven the result of obstruction. Some cases occur many years after injury. The majority occur without known cause.

The symptoms are more or less those of an ordinary coryza, together with a feeling of disten-

sion, exophthalmos, diplopia, failure of eyesight, and the appearance of a tumor over the superciliary ridge or at the root of the nose. Hard at first, this soon becomes soft and fluctuating. The only treatment is to make an external opening and an opening into nose through which a perforated rubber tube should be passed. Cleanliness and free drainage are most important. Of twenty-five cases so treated cure resulted in twenty-three; in two result was not stated; while when drainage into nose was neglected, the results were not nearly so good. Death occurred in six cases: in four from secondary cerebral abscess, in another from meningitis, and in the last from albuminuria.

DR. A. B. THRASHER, of Cincinnati, read a paper on *Morbid Perforations of Nasal Septum*. The author reported sixteen cases of morbid perforation of septum narium, having special reference to the syphilitic theory of the origin of the disease. Three of the cases occurred in syphilitics, eleven where syphilis had not been present, and two cases were doubtful. In the syphilitic cases the vomer and at least one of the turbinates was invariably attacked; and pain was always felt when this was the case. In the non-syphilitic cases the perforation, as a rule, gave rise to no symptoms; at times seemed to have been caused by picking the nose with finger-nail. There was localized anæsthesia in the ulcerated area, the application of the galvano-cautery producing no pain. The treatment consisted, locally, in detergents, canstics to the ulcerated area, and mild ointments; internal, in remedies addressed to the underlying dyscrasia.

DR. CARL SEILER, of Philadelphia, read a paper on *Clinical Observations on some Cases of a Peculiar Character*, in which he describes the symptoms of a disease not yet well known. He had not seen Dr. W. C. Glasgow's paper read at the Medical Congress at Washington last autumn before the Laryngological Section, and therefore confined his remarks to his own personal observations.

The run of symptoms of cases observed by the author are summed up as follows: 1. Neuralgic muscular pains, usually in the back and chest, and often in the head, ears and limbs. 2. Extreme debility. 3. Mucoid infiltration of the submucous tissue and the formation of thin white pseudo-membranous patches on the surface of the mucous membrane. 4. Absence of febrile symptoms at first, and later high temperature and relatively low rate of pulse. 5. Absence of albumen in the urine and liability to heart failure. 6. Gradual melting away of the pseudo-membranes and the absence of any odor from them. 7. The wide geographical distribution in this country and the infectious, but not contagious, nature of the disorder. 8, and finally, The specific action of benzoate of soda in relieving the symptoms promptly.

DR. E. S. SHURLEY, of Detroit, Mich., read a paper on *The Hot Air Treatment of Phthisis*. The paper was for the purpose simply of reporting progress in the use of the Weigert apparatus, and suggesting certain indications for its future trial. The author had used the apparatus in about twenty patients, in about eight with that constancy and exclusiveness that would serve as a test.

*Case 1.*—Obligated to discontinue the treatment from the pain experienced in the throat and chest from the inhalations.

*Case 2.*—Administered three and four times a day for fifteen minutes. Temperature  $120^{\circ}$  to  $200^{\circ}$ —the latter on three occasions only;  $130^{\circ}$  to  $190^{\circ}$  on several. Immediate effects good; left hospital *improved*.

*Case 3.*—Inhalations caused nausea and vomiting. Hectic fever decreased, gained strength and flesh.

*Case 4.*—Caused febrile movement, pain in chest, breathlessness and nausea at  $120^{\circ}$ . Discontinued after ten days.

*Case 5.*—Laryngeal and pulmonary phthisis. Administered for a week; could not bear it longer.

*Case 6.*—Advanced stage of phthisis. Administered three times a day for twenty-five minutes at a time—could not bear it and it was omitted.

*Case 7.*—Effects good.

*Case 8.*—Obligated to discontinue after fourteen days from loss of appetite, apparently resulting from the administration of hot air.

The author had found it impossible to apply the method of treatment for such a length of time as reported to have been done in Germany.

DR. W. K. SIMPSON, of New York, gave the *History of a Case of Acute Rheumatic Laryngitis of Gonorrhœal Origin*. The history is presented on account of extreme rarity of the case—have been unable to find references to similar case. The patient was first seen on February 23, 1888, at which time these notes were taken. Gave the history of two previous attacks of gonorrhœa, has had present attack of gonorrhœa for last five weeks. Three weeks ago began to have rheumatic pains and stiffness in both knees and hips. Three days ago pain and swelling began in left thumb and wrist, so that they now present the typical swelling of acute rheumatic inflammation. Laryngeal symptoms began three days ago, with painful deglutition; on following day there was a painful swelling of lower external portion of larynx. In the evening patient became very hoarse and breathing became very painful.

February 23, 1888. Examination of the throat to-day revealed painful deglutition, pain on pressure over right side of pharynx, absence of cough. Internally both arytenoids swollen and red, right much in excess, it being somewhat œdematous, and is, with the right vocal cord, immobile on phonation. Whole of anterior portion of larynx more or less hyperæmic, the right vocal cord

being of a deep purple color and considerably swollen.

Treatment consisted of ac. salicyl., which did not prove effective. Internal laryngeal swelling increased, embarrassing respiration. On February 29 a blister was applied to external larynx and patient placed on iod. of potass., and by March 6 had improved greatly in laryngeal symptoms, but there still remained very little motion of the right arytenoid and cord, and they were both still very red.

## FOREIGN CORRESPONDENCE.

### LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

*The Father Damien Memorial Meeting at the Mansion House—Picrotoxin as an Antidote to Morphine—Honors to Sir Andrew Clark—The Lord Mayor Inaugurates a Fund for the Pasteur Institute—A New Method of Disposing of the Dead—A New First Field Dressing—The New Commissioner in Lunacy—Consumption can be Transmitted to Human Beings through Milk.*

The first meeting of the committee for promoting a memorial of Father Damien has been held at Marlborough House, under the presidency of the Prince of Wales. The proposal is to erect a monument to the deceased missionary over his grave at Molokai, to establish a leper ward in one of the London hospitals, to endow one or two traveling studentships for the special study of leprosy, and finally to set on foot a full and exhaustive inquiry into the whole question of leprosy in India. It is calculated that there are in the Indian Empire about 250,000 victims of the loathsome scourge, or about one-thousandth part of the whole population, while in the British Colonies it is infrequent, but it is said to be spreading. The Prince of Wales mentioned one startling instance of its presence in England: "At this very moment," said he, "there is a leper with his hands distinctly affected by the disease, engaged at his business in one of the large London meat markets." Sir James Paget in a speech expressed the hope, that the designed stimulus to trained investigation might lead ultimately to the abolition of leprosy. At one time as he observed leprosy prevailed extensively in England and in the west of Europe, and he considered that its gradual elimination is after all not an impossibility. At one time there were six or eight hospitals for lepers in London. The victims were scattered all over England, and there were large numbers in France. Sir James thought that the only way in which it could be reached where it now prevailed was by scientific inquiry, and by improved methods of treatment.

Looking back over the last fifty years, it certainly might be said that more remarkable things had been accomplished than would now be accomplished if leprosy were abolished.

Picrotoxin is now recommended as the best antidote to morphine. The effect of morphine is, of course, to paralyze the action of the respiratory centre; picrotoxin on the contrary, when given in small doses increases such action. Thus the two drugs act in a directly opposite way. An overdose of morphine produces paralysis of the respiratory organs, picrotoxin prevents such paralysis. Picrotoxin stimulates the vaso-constrictor centre of the medulla, and thus counteracts the diminution of the blood pressure due to an overdose of morphine. These two agents again have an entirely opposite effect upon the cerebral hemispheres. Experiments are being made as to the use of the drug in the prevention of asphyxia from chloroform.

The Duke of Cambridge has consented to present to Sir Andrew Clark the senior consulting physician of the London Hospital, his portrait by the late Frank Holl, which was exhibited at the Royal Academy exhibition last year, and subscribed for by the medical and surgical staff and friends of the hospital. A replica of the painting will at the same time be presented to the College of the London Hospital Medical School.

The Lord Mayor was so struck with the Pasteur Institute which he visited while in Paris, that he has called a meeting at the Mansion House to inaugurate a fund for its benefit. The Prince of Wales also paid a visit to the institute during his recent stay in Paris, and was much interested in all he saw. At the same time, as far as hydrophobia is concerned, many authorities on the subject are resolutely opposed to any Pasteur Institute being established in England, contending that by the strict use of the muzzle and a system of quarantine with regard to all dogs imported into Great Britain rabies can be effectually stamped out, the insular position of the country giving it an advantage in this respect not possessed by Continental countries.

A physician whose name does not transpire, has, it is stated, suggested a new method of disposing of our dead, which to say the least, is broadly original, even if it has poor opportunity of becoming popular. In all seriousness the following process is suggested. The doctor proposes to deal with the deceased by means of hydraulic pressure, and in a very short time to reduce him to a cube of twelve inches, a solid block of handsome material resembling veined marble, tasteless, odorless and apparently imperishable. The doctor is stated to have on exhibition a capital cross suitable for a lady's dressing-room. It would at least be interesting to know this gentleman's name, and to see the result of, say one experiment.

A new "first field dressing" devised by Surgeon-Major Bourke, of the Army Medical Staff, is about to be generally adopted in the army. The pad is about 5 inches by 3½ inches, and the bandage about 1¼ or 1½ yards in length, the former being composed of layers of cotton-wool, and the latter of soft cotton gauze. Both are rendered antiseptic by being evenly impregnated with double chloride of mercury and ammonium, which for surgical purposes, has many advantages as compared with sublimate. With each of these pads is supplied a safety-pin and a little bag of iodoform powder for "dusting" purposes.

The new Commissioner in Lunacy, Dr. Thos. Clifford Allbutt, is one of the most distinguished physicians in the whole of Yorkshire, and his enforced removal from Leeds is regretted by ever so many people in that great manufacturing town. Dr. Clifford Allbutt is a man of about 50, with fair hair, and singularly light eyelashes. He received his education, medical and general, at Cambridge—of which University he is an M.A.,—St. George's and Paris, and is F.R.S., F.S.A. He has been consulting physician to various public institutions in Leeds and the neighborhood, and has enjoyed a very large private practice, indeed, it is said of not far off £10,000 a year. As a lunacy commissioner Dr. Allbutt will get only £1,500, but of course a man of his great scientific attainments looks at the matter from the point of view of Kudos as well as of Kerdos. Dr. Allbutt has paid much attention to mental pathology.

Dr. Imlach, of Liverpool, who has given a good deal of attention to the subject, has come to the conclusion that consumption can be transmitted from cows to human beings through milk. His experiments prove that guinea pigs, rabbits and monkeys fed on the milk of tuberculous cows develop tubercular disease.

It may not be generally known that until the sixteenth century alcohol was used only as medicine. It was as a drug, and not as a beverage, that it became known as aqua vita, from its great restorative powers. In 1681 it was first introduced as part of the food allowance of the British Army in the Netherlands. G. O. M.

## NEW INSTRUMENTS.

### IMPROVED VAGINAL DEPRESSOR SPECULUM.

BY HENRY O. MARCY, A.M., M.D., L.L.D.,  
OF BOSTON.

The general adoption of irrigation during surgical operations has materially modified the practice of most American gynecologists in operative measures upon the uterus and vagina; the Sims' speculum and semi-prone position often being very inconvenient.

The patient upon the back, with the hips well over the edge of the table, limbs held by the Clovis' crotch, or some modification of it, furnishes the most convenient position. The depressor in more general use in the one known as the Martin speculum, devised by Dr. A. Martin, of Berlin. This has been found inconvenient and objectionable, because the solid handle causes the drip from the irrigator to flow over the hand and down the arm of the holder, and the breadth of the blade is widest at the vulvar extremity. This often produces overstrain of the vaginal outlet, with frequent lesions, and also occupies valuable space required for operative measures.

Dr. Marcy has sought to overcome these objections in the instrument which he offers to the profession.

Because of its simplicity there is little need for explanation. The vaginal portion is constructed so as to cause a minimum of pressure upon the vulvar outlet. It is irregularly broadened within, so as to secure a firm hold upon the levator muscular loop without slipping, and this allows of depression without overstrain of the external parts, and permits the foreshortening of the instrument to the minimum, scarcely more than one inch in length.

When the uterus is of normal mobility the cervix can be easily brought to the vulva. By its use the anterior vaginal wall and the uterus are rendered much more accessible. The handle is made hollow for the escape of the irrigating fluid and roughened for a secure hold. The speculum is well made and kept in stock by Messrs. Codman & Shurtleff, of Boston, and Tiemann & Co., of New York.

## NECROLOGY.

### Francis M. Urquhart, M.D.

Francis M. Urquhart, Passed Assistant Surgeon U.S. Marine-Hospital Service, was born in Southampton County, Va., December 3, 1857, and died at Evansville, Indiana, February 14, 1889. Dr. Urquhart received his early education in Hanover Academy, Hanover County, Va., and subsequently entered the medical department of the University of Virginia, from which he graduated in the spring of 1878. He pursued the study of medicine one year in New York City under Dr. John A. Hyeth, and there entered the Charity Hospital of that city, where he remained two

years. In the spring of 1881 he appeared before the Board of Examiners of the Marine-Hospital Service, which he passed successfully, and was appointed to the Service as an assistant surgeon, October 20, 1881. He was assigned to duty in the Marine Hospital at New York, and served at that station until April, 1882, when he was transferred to St. Louis, Mo., where he remained till January, 1885, except when upon temporary details at other forts. In December, 1884, he was promoted to the position of Passed Assistant Surgeon. During the summer of 1885, '86, '87 and part of 1888, he was placed in charge of the Quarantine Station at Cape Charles, Va. In August, 1888, he was detailed for special duty in the yellow fever districts of the South, and was successively stationed at Way Cross, Ga., Dupont, Ga., and Live Oak, Fla. In November, 1888, he was ordered to Evansville, Ind., on temporary duty, and while under orders for Buffalo, N.Y., died at the former station, where he was taken sick soon after his arrival. A low form of fever of nearly two months' duration, followed by a relapse and subsequent pneumonia, ended his career. Dr. Urquhart took a high rank in the Service, and enjoyed the confidence of his superior officers, whose orders he obeyed with alacrity. He married Lizzie M. French, of Boston, Mass., in September last, while still on duty at the South, and his bride was with him during his long illness at Evansville, Ind., where he died.

## BOOK REVIEWS.

THE RADICAL CURE OF HERNIA. By HENRY O. MARCY, A.M., M.D., LL.D. The Physicians Leisure Library. Detroit Mich.: George S. Davis.

A highly interesting and well written volume of 251 pages, illustrated by eighteen woodcuts. In this work each form of hernia receives attention proportionate to its importance. Not only is the subject taken up from an anatomical and surgical point of view, but our obligations to our predecessors are not ignored. The voluminous history of this important subject is very ingeniously brought together, and so well told that we trace its progress step by step, to the perfect methods of to-day. The views and modes of operating among the most eminent of modern surgeons both here and abroad are fully given. Important results have been brought about by simply modifying the various steps in this operation so that they are more consistent with the maintenance of a perfect aseptic condition. There are four steps to be considered:

1. The mode of incision.
2. The treatment of the sack.
3. The application and choice of

sutures. 4. The treatment of the wound. The author advocates the open wound method. In inguinal hernia he frees the sack, sutures it as high up as possible with the double continuous suture, and cuts away that portion below. All is closed in with the buried animal suture, and kept in a thoroughly aseptic condition. If this is maintained no drainage has been found to be necessary.

In studying the action of various forms of animal sutures buried in the tissues, the author has done no little to advance this branch of surgery. As early as 1870 he had demonstrated experimentally that aseptically applied animal sutures became so incorporated into the vital structures as to be, in a large measure, replaced by connective tissue. It was found that the absorption of catgut often progressed too rapidly, and the parts were left too early without sufficient support, hence the tendon from many animals was experimented with, and various modes of preparation tried. The author has used tendon from the tail of the kangaroo for the past seven years, and finds it all that could be desired.

The reports of operators quoted give 779 cases operated upon with only five deaths, and these are explained as being produced by causes other than the operation.

## MISCELLANY.

AMERICAN RHINOLOGICAL ASSOCIATION.—Owing to the absence of a number of the Fellows of the American Rhinological Association in Europe, and the Pacific Coast, the annual meeting will be postponed until October 9, 10 and 11, 1889, at which time it will be held at the Palmer House, Chicago, Ill.

THREE HUNDRED NEW READERS.—THE JOURNAL has added to its mail list, since July 1, over 300 new names. The weekly issue is now 5,200.

## LETTERS RECEIVED.

### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from July 20, 1889, to July 26, 1889.*

By direction of the Secretary of War, Major William H. Gardner, Surgeon, is detailed to attend the encampment of the National Guards of the District of the Columbia, at Ft. Washington, Md., from July 22 to 29, 1889, for the purpose of giving instructions to the medical officers and hospital corps in their respective duties. Par. 1, S. O. 164, A. G. O., July 18, 1889.

By direction of the Secretary of War, Capt. Wm. R. Steinmetz, Asst. Surgeon, now at Baltimore, Md., on leave of absence on account of disability, will report in person to the commanding officer of the Watertown Arsenal, Mass., for duty at that station, relieving Lieut.-Col. James C. McKee, Surgeon. Par. 3, S. O. 166, A. G. O., July 20, 1889.

Lieut.-Col. McKee, on being relieved at the Watertown Arsenal, will repair to Philadelphia, Pa., and assume the duties of attending surgeon and examiner of recruits in that city. Par. 3, S. O. 166, A. G. O., July 25, 1889.

Capt. Samuel Q. Robinson, Asst. Surgeon U. S. A., Ft. Hamilton, N. Y. H., is hereby granted leave of absence for two weeks. Par. 11, S. O. 165, Hdqrs. Div. of the Atlantic, July 22, 1889.

Lieut. R. R. Ball, Asst. Surgeon U. S. Army, leave of absence granted in S. O. 87, Dept. of the Missouri, July 9, is extended five days. Par. 1, S. O. 167, A. G. O., July 22, 1889.

### PROMOTION.

Asst. Surgeon Charles B. Ewing, to be Asst. Surgeon with the rank of Captain, after five years' service, in accordance with the Act of June 23, 1884. July 5, 1889.

By direction of the President, the State of Arkansas, embracing Little Rock Barracks, is transferred to the Department of the Missouri. General Orders No. 66, Hdqrs. of the Army, A. G. O., July 19, 1889.

### *Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service. Omitted from last Announcement.*

Surgeon John Vansant, when relieved, to proceed to Mobile, Ala. July 11, 1889.

P. A. Surgeon F. W. Mead, relieved from duty as acting Chief Clerk and attending surgeon; ordered to St. Louis, Mo., July 11, 1889.

P. A. Surgeon L. L. Williams, relieved from duty at Cape Charles Quarantine Station; ordered to Baltimore, Md. July 10, 1889.

### *Week Ending July 20, 1889:*

P. A. Surgeon P. C. Kalloch, granted leave of absence for thirty days. July 15, 1889.

Asst. Surgeon W. J. Pettus, when relieved, to proceed to Marine Hospital, Boston, Mass., for duty. July 18, 1889.

Asst. Surgeon R. M. Woodward, granted leave of absence for thirty days. July 15, 1889.

Asst. Surgeon G. T. Vaughan, relieved from duty at Boston, Mass.; ordered to Norfolk, Va. July 18, 1889.

Asst. Surgeon J. B. Stoner, granted leave of absence for twenty-five days. July 15, 1889.

Asst. Surgeon H. D. Geddings, relieved from duty at Baltimore, Md.; ordered to Key West Quarantine Station. July 18, 1889.

Asst. Surgeon C. P. Wertenbaker, relieved from duty at Norfolk; ordered to Galveston, Tex. July 18, 1889.

J. T. Groenevelt, commissioned as Asst. Surgeon July 14, 1889. Ordered to Gulf Quarantine Station for temporary duty. July 20, 1889.

ORIGINAL ARTICLES.

CONCUSSION OF THE SPINE IN ITS  
MEDICO-LEGAL ASPECTS.

*Read in the Section of Surgery and Anatomy at the Fortyeth Annual Meeting of the American Medical Association, held at Newport, June 25, 1889.*

BY HENRY HOLLINGSWORTH SMITH,  
M.D., L.L.D.,  
OF PHILADELPHIA.

The legal liability of Capitalists and Corporations to be charged with claims for pecuniary damages in cases of injuries received by individuals through a claimed negligence, was established by the English Parliament in the year 1846, and is widely known as Lord Campbell's "Liability Act." Somewhat similar statutes were subsequently enacted by the State Legislatures of this country, and this responsibility on the part of carriers and employers is generally regarded as wise and tending to the proper protection of life and limb.

In Great Britain the "liability act" is the same throughout the Kingdom, but in the United States it varies somewhat in different States, especially in the amount of damages that can be claimed. In Michigan the limit of a claim is fixed at \$5,000; in New York it is \$10,000; in Mississippi it is such compensation as shall be deemed fair and just in reference to the injury sustained by the plaintiff. In Tennessee it includes mental and physical suffering, loss of time, necessary expenses of the deceased and damages to the beneficiary, but in Pennsylvania, since the adoption of the new Constitution, there is no limit. In one case, in Philadelphia, the loss of a leg by a newsboy on a passenger railway was assessed by a jury at \$18,000; appealed to the Supreme Court, a new trial was ordered and a verdict for \$20,000 given, and this verdict has been paid. Another child, 8 years old, was awarded \$16,000 for injuries caused by tripping over a stone left on the sidewalk by the City Corporation, and very many other cases could be cited.

So generally is this liability for injury caused by negligence, admitted, that most corporations or employers do not hesitate at a prompt settle-

ment of a just and reasonable claim, being influenced thereto not only by a proper regard for the suffering induced, but also as an acknowledgment of "the Majesty of the Law," it being now a well-settled principle "that they are liable for past and future physical and mental suffering, together with the loss of earning power where the consequences are such as in the ordinary course of nature may be reasonably expected to ensue."<sup>1</sup>

It is, therefore, not unusual for conductors, foremen, or other servants of corporations, to be instructed in the event of injuries received, to do all that is possible to ameliorate the sufferer's condition. Many companies have also surgeons regularly employed to render immediate professional attendance.

A recent example of the disposition of a corporation to promptly relieve suffering and settle a just pecuniary demand for injuries received in transit, is shown by the action of the Lehigh Valley Railroad, of Pennsylvania, where, after an accident to an excursion train at "Mud Run," in October 30, 1888, in which 63 persons were killed and over 80 others wounded, the company made a prompt and amicable settlement with most of the claimants, at a cost of over \$150,000, though the Coroner's Jury, after a rigorous examination of the case, failed to report any want of care or proper vigilance on the part of those in charge of the train.

Under the "liability law" a refusal to pay what may be regarded as a doubtful or extravagant demand, usually carries the claim into Court and confides it to the judgment of a not over-intelligent jury, who often appear to have an innate prejudice against all corporations or capitalists. In these cases the medical testimony as to the nature and probable result of the injury claimed to have been received, becomes often the turning point on which a just award can be given. The medical expert then, who correctly appreciates his responsible position, should keep himself thoroughly abreast with the progress of science and endeavor to exercise such judicial power as will enable him to hold the scales of justice so level that the preponderance of the medical facts once established, may correctly in-

<sup>1</sup> *Patterson, "Railway Accident Law," Philadelphia, 1886.*

cline the balance to the right side and lead a jury to a true and impartial verdict for that side to which it properly turns.

As many corporations have surgeons regularly engaged to serve them in these accidents, it is desirable that the correct position of such experts should be clearly defined, and the following judicial opinion on the "relation of scientific experts to the administration of the law," has recently been so well expressed by a Judge of the New York Supreme Court<sup>2</sup> (in regard to these duties and relations), that I repeat them in a condensed form. "In an action for damage," says Judge Willard Bartlett, "arising from accidents on railroads, the respective parties are often assisted by Surgeons, who testify to the nature, extent and consequences of the plaintiff's injury, and also often advise counsel as to the conduct of the surgical part of the case. A wise doctor should, however, take care not to act in both capacities. If he testify, he should not act as assistant counsel, and if he acts as assistant counsel he should keep off the witness stand, because he will naturally become prejudiced in favor of the party in whose service he is acting, and the jury will regard such a witness as prejudiced and his testimony as that of a partisan, thus materially detracting from the force and effect of his evidence. The attitude of the physician called as an expert, should be as nearly as possible one of entire impartiality as between the litigants." Judge Bartlett also says, "I have every reason to believe that cases are not unknown in which the plaintiff's counsel have said to a physician, 'I think my client's injuries are serious. Go and see him for me. If you find that he is not seriously hurt, I shall not expect you to charge me anything for making the examination, but if you conclude that his injuries are incurable, I will call you as a witness and pay you handsomely.' As this is manifestly incorrect, no such proposition would be accepted by a really honorable professional man of high character."

Unfortunately for justice, the medical testimony is often so conflicting that neither Judge nor Jury can properly estimate it. This diversity of opinion is sometimes due to the want of a proper study of a case, or, the varied experience and moral tone of the expert (and his views of right and duty between man and man), as well as to the fact that the science of medicine being always progressive, there is no fixed point on which an expert's opinion can be securely based, and *Page* has well said,<sup>3</sup> "there must ever be differences of opinion in matters so difficult as the investigation of disease, but it is wholly possible to be impartial," whilst *Erichsen* says: (2)

"Conflicts of opinion on certain points are creditable to the independence of thought and the individual self-reliance that characterizes professional opinion."

The progress of microscopical, physiological or pathological studies of tissues, especially of the nervous system and the regional localization of the functions of the brain and Spinal Cord, which are peculiarly liable either directly or indirectly to be affected by these injuries, also tends to show that the professional opinions held twenty years since are now in many points incorrect and unreliable and those of *Mr. Erichsen* on "Railway Injuries and Concussion of the Spine," once often quoted, are mistrusted by many, who deny the correctness of his terms and object to his combination of different injuries under the one title of "Concussion of the Spine."

As every period of Court in our large cities presents one or more claims for personal injury, in which the results of concussion of the spine are often presented in an exaggerated form by Counsel (in what has been well designated as "Litigation Symptoms") to cover or sustain claims that could not otherwise be established as of sufficient magnitude to justify punitive or exemplary damages, it becomes important to settle, if possible, whether the so-called "Concussion of the Spine," "Railway Spine," or "Railway Brain," can exist, and if so, whether the so-called "Railway Spine" presents a special train of symptoms differing in any point from those induced by other forces than railway collision, and although many local societies and individuals have for years investigated these cases and their results, I desire now to present the question for the discussion of this Section in order to elicit a wide expression of the sentiments of those who here represent the surgical skill of the whole United States.

It is unfortunate that the consideration of the subject of "Concussion of the Spine" should be so much handicapped by the legal aspect given to it in the cases presented in claims in court; these cases frequently offering less marked symptoms than those met with in hospitals or private life where there is no prospect of the sufferer receiving an award from a jury. Formerly such claims could not be presented by *employés* and suits by them were rare. Thus prior to 1871 the German railroads were not liable for injury to their *employés* and the latter, being anxious to keep their places and gain their living, managed by an energetic effort of the will, to overcome and control their nervous condition; but as soon as the laws of Germany made corporations liable to their *employés*, the number of suits instituted from 1871 to 1876, on one railroad only, was at least nine times larger than before. Thus in fifteen derailments before 1871 there were but two injuries leading to claims for disability, whilst subse-

<sup>3</sup> Injuries of the Spine and Spinal Cord without Apparent Mechanical Lesion and Nervous Shock, by *Herbert W. Page*. Second Edition, London, 1885.

quently to 1871 seven derailments occasioned eighteen lawsuits.\*

In all suits for damages for concussion of the spine it should be recollected that *fraud* on the part of a claimant is quite a common item in the legal investigation of this injury, and thus *Page* reports<sup>5</sup> "234 cases, in a large majority of which there was either fraud or an exaggerated claim, as proved by subsequent history." *Hodges* reports,<sup>6</sup> that "in 21 cases where so-called symptoms of concussion of the spine were alleged to be present and were under his personal care, 10 are believed to have been proved deceptions; whilst in 6 a diagnosis as to deception was doubtful. Of 28 similar cases reported by *Rigler*, 7 were found to be simulated and in 13 the diagnosis in regard to fraud was doubtful. Of these 49 cases, 36, or three-fourths of the whole number, were really or probably deceptions." *Hodges* also cites<sup>7</sup> the following cases illustrative of fraudulent claims and unjust awards by juries.

"In 1872 the Metropolitan Railroad, of Boston, Mass., was mulcted by a jury in a sum of \$10,000 in the case of a man whose detailed symptoms satisfied them that he was utterly enfeebled in body and wholly unable to earn his own living. At the close of the trial the plaintiff celebrated his victory by becoming uproariously drunk, and it required the united strength of three policemen to take him to the Station House. In another suit in which there was a claim of impotency resulting from the injury, the jury expressed their sympathy by a verdict of \$18,000, yet not long afterwards the man was convicted of bastardy."

*Judge Wilson*, of the Court of Common Pleas, Philadelphia, also says,<sup>8</sup> "I have in my mind a case where a very badly injured person was *substituted* at the trial and large damages obtained, whilst the real plaintiff was not injured at all."

The following case in my own practice illustrates an exaggerated claim and the liability of a surgeon to be deceived, either by a malingerer or hysterical man, when he places faith in the subjective symptoms presented by the claimant and apparently seconded by circumstances.

*Case.*—W., age 35 years, married, in full health at the time of the accident, claimed injuries from colliding trains at Havre de Grace, P.W. & B. road, on June 21, 1887. On Sept. 14, 1887, about three months subsequently, he exhibited three scars, one deep in the forehead and left eye-brow and a deep scar on the left of the upper lip, which he stated were the result of blows. He also exhibited a superficial scar from a wound on the inside of the right knee, not penetrating the joint; the patella bursa of this knee was also swollen, and he claimed to have been struck in the back, re-

ceiving a dark bruise that extended from the top of the shoulder to near the right hip. Of this bruise there was, on September 14th, no evidence, but there was apparent nervous disturbance, his right arm seeming to be paralyzed in motion and sensation, though his grip was fair. His memory, he said, was enfeebled, and he denied knowing what he had eaten for breakfast on the day of my examination. He also reported having been insensible for nearly four hours after the blow; that he was taken by train to Washington, D. C., and treated there; but that subsequently he was well enough to travel to Maine to escape the heat of the summer, and was improved by the trip. After full consultation with his family physician (Dr. Meccray, of Camden, N. J.), I reported to the railroad company that he had received the above injuries, but that the permanent disability claimed was not sustained by the evidence, as he was then apparently recovering. This opinion not being satisfactory to the plaintiff's lawyer, I was again requested to make a survey and report, on September 22, 1887. After a second examination and consultation with Dr. Meccray, I reported a slight improvement in the power and sensation of his limbs, as he now walked downstairs to his parlor and walked there with slight assistance, dragging his right foot a little and with his right arm drooping. His mind was also clear and he recalled events during his stay in Washington, D. C. I therefore gave an opinion, renewing my former statement, and mentioned the benefit apparent from his physician's treatment; that the patient complained of the tediousness of his confinement and was anxious to return to work, and that his doing so would probably advance his recovery.

Two months after this (November 11, 1887), Dr. Meccray wrote me:

"You will remember on your second visit to Mr. W. we were both inclined to give a favorable prognosis, as he was then able to walk about the house, to take moderate exercise, and was free from suffering, except from neuralgia of the left side of his head. Since then there has been a marked increase in the unfavorable symptoms." (The settlement of his extravagant claim for damages, \$15,000, was now becoming doubtful, the claim being for permanent disability.) "The paralysis of the right side," said Dr. Meccray, "has much increased, the right arm is entirely helpless, with the exception of a slight grip of the hand. The power of the right leg is totally gone, and there are no reflexes whatever. The urine dribbles from the bladder, the bowels are constipated, though under his control; vision in the left eye and hearing in the left ear are now much impaired; in fact I look upon his case as one of '*progressive and permanent paralysis*,' the result of pressure upon his spinal cord, possibly a breaking down of some of its tissues. His memory, I think, is

slightly improved. He is confined to his bed and I fear will end his days there. Dr. D. Hayes Agnew, of Philadelphia, has seen him with me and concurs in my opinion. If you have any suggestions I will be pleased to hear from you." [Signed, A. M. MECCRAY.]

On November 12, 1887, I again visited Mr. W., and had a third consultation with his attending physician, reporting to the company "that since my former visit from some unexplained cause Mr. W. had greatly deteriorated in health. For some weeks he reported himself unable to leave his bed for any purpose and is now apparently suffering, as his physician states, from "progressive paralysis." He has no motion in either arm, except in his fingers, nor is there motion in the lower right limb. Sensation on the right side is nearly destroyed, he giving no shrinking from the puncture of the skin by a pin thrust in till it brought blood. The left limbs are sensitive. His bladder is partially paralyzed; his urine dribbles from him, and he uses a bed-pan to evacuate his bowels, being unable to rise. He is very tremulous and nervous, with depressed circulation and more mental aberration." With this report I forwarded to the company the suggestion of delay in the settlement of the claim as the patient's condition, though then unfavorable, might be improved by time. Whilst giving much weight to the opinion of his physician, who saw him daily, I was yet unable satisfactorily to account for the deterioration in his condition, the respectability of his domestic surroundings and his own standing precluding the idea of malingering. The possibility of hysteria, as claimed by Charcot in such cases did not occur to me at this time. With this evidence from his medical attendants, his claim was abated and compromised by the company on January 19, 1888, for \$8,500. Six months subsequent to this, being doubtful of the result of his case, and desirous of satisfying myself of his ultimate condition, I wrote to Dr. Meccray asking his report to date, "for the cause of science," and on the 11th day of April, 1889, was informed by him that on *the day after the payment of the claim* Mr. W. arose from his bed, travelled to Washington, and in a few weeks was able to attend to his usual avocations. Was this a case of successful malingering, or was it paralysis from hysteria? It certainly was not, as supposed by the surgeons, "progressive paralysis;" though closely resembling it.

Admitting the liability of a surgeon to be misled in his Diagnosis and Prognosis of cases claiming to be the result of spinal injuries, it may be asked, 1st. Can any force be so applied as to produce a concussion of the spinal cord? 2d. How are the normal functions of the cord disturbed by such injury? 3d. What pathological changes in the cord result from its concussion?

1. Can any force be so applied as to produce

concussion of the spinal cord and its nerves? Concussion of the spinal cord from any violence sufficient to disturb its functions, whether by falls, blows on the back, or shaking and collision or derailment of cars, must be admitted as *possible*, as it is now demonstrated by post-mortem examination; but the violence must be greater than that sometimes created in coupling a locomotive to a train, claims for which I have frequently known to be made.

2. How are the normal functions of the cord disturbed by such injuries? Disturbance of the normal functions of the cord, or the symptoms of its concussion, can be recognized by evidences indicating a modification of normal cessation or motion in varied degrees as shown through the peripheral nerves. H. Fischer has recently suggested that the condition known to surgeons as "*shock*" is a traumatic reflex paralysis of the vascular nerves, the "*concussion of the brain*" being simply a shock localized in the brain, a traumatic reflex paralysis of the cerebral vessels, and *L. Schöle* applies this view directly to "concussion of the spinal cord." *Erb*, however, regards the symptoms of concussion of the cord as due to "molecular disturbance, and thinks this is the chief element in its concussion."

Reference to the normal action of the cord best illustrates these symptoms.

According to *Erb*<sup>10</sup> "all impressions made in any way on the peripheral nerves are conducted to the posterior or anterior roots of the spinal nerves and pass thence into the lateral columns of the cord and thence to the brain, as touch, temperature, tickling, etc. The sensation of *pain* is conducted exclusively by the gray substance of the cord. The *sensory* impressions decussate in the cord and medulla oblongata and *voluntary* movements pass *from* the brain to the cord, through the decussation at the pyramids, medulla oblongata and pons varolii."

The seat of the coördination of *movement* is not settled, but is supposed to lie only in the brain, the cord only transmitting the coördinate impulse to the muscles.

The centre of *vaso-motor innervation* lies in the cord and medulla, and Charcot says, "the nutrition of the peripheral nerves, muscles, bones, joints, skin, hair, nails, etc., is dependent on the action of the spinal cord," and of course these are impaired by its injury.

The disturbance of the function of the cord by injury or disease will, therefore, be noted (a) in disturbance of the normal *sensibility*, as anæsthesia, hyperæsthesia, paræsthesia; or abnormal sensations, as pain, either lancinating or neuralgic; (b) in disturbance of *motility* as shown in weakness or paralysis, or ataxia; or by increased mo-

<sup>9</sup> Volkman's Sammlung Klinische Vorträge, Nos. 10 and 27, as quoted by *Erb*.

<sup>10</sup> *Erb*, Diseases of the Spinal Cord, p. 352, and from this monograph much that I have stated is condensed.

tility, as in spasms or twitching; (c) vaso-motor disturbance will be shown, in hyperæmia, increased redness with elevation of temperature and modified sensation, as in the old "rubor, dolor, calor" of inflammation, accompanied often by modified nutrition of the tissue affected.

3. What pathological changes in the cord are found as due to its injury or disease? Pathological changes may be noted first, in the disordered action of the blood-vessels concerned in the nutrition of the membranes and of the cord as (a), congestion or hyperæmia; hæmorrhages or effused blood; inflammation of the membranes or of the component cells of the spinal cord; (b), in anæmia; or we may have myelitis followed by softening or sclerosis; or (c), there may be changes due to malignant diseases or tumors, omitting all reference to changes from mechanical action, as wounds, fractures, or luxations of the bones forming the spinal canal.

The disturbed function of a spinal cord may, however, also be "due to a diseased or neuropathic disposition, either inherited or acquired, as by sexual excesses, which are common; exposure to cold and wet; intoxication; syphilis; excessive exertion and overtaxed muscle; acute diseases, as the exanthemata; fevers and pneumonia," so that in studying the results claimed as due to a concussion of the spine from injury, and especially in litigation cases for damages, too much care cannot be exercised in obtaining a full and correct history of the claimant *before* the accident and in a careful analysis of the subjective symptoms, so as to prove that the injury did not create them. If the disturbance is *functional* it can be cured and there may be no permanent disability. When a claimant is impecunious and seeks to repair his fortunes by a demand on a corporation or capitalist, the expert should carefully eliminate all symptoms not evidently free from the disorders of the spinal cord due to preëxisting diseased conditions, or show to what extent the accident was connected with them.

As Neurasthenia or *functional* disorder of the cord can produce all the symptoms often ascribed to violence, may we not doubt the correctness of Erichsen's opinion<sup>11</sup> in ascribing such symptoms to "concussion of the spine." Such doubts are daily becoming more numerous, and the varied nervous symptoms alluded to by him are assigned by more modern authorities to other causes. Thus Charcot says:<sup>12</sup> "The obstinate symptoms resulting from railway injuries are *hysteria* (or hysterical) and nothing else," and hysteria, according to Dr. Ozeretokofski, of Moscow, "is by no means an exceptional occurrence in men, presenting the same diversities in them that it does among women;" he having studied no less than thirty-

eight cases in the Moscow Military Hospital.<sup>13</sup>

The correctness of the opinion that concussion of the spine is common and creates special symptoms, has also been doubted by others; thus *Bramwell* says:<sup>14</sup> "Whilst I am not prepared to deny the occurrence of simple concussion of the spine, I am disposed to doubt whether organic disease can or does result from it. Indeed, everything seems to show that when disease of the cord results from external violence, the disturbance of its functions depends, from the first, on definite and distinct alterations of structure; and there is good reason for supposing, that undoubted and severe disturbance of the spinal function *rarely* results from violence; the ordinary type of chronic disease of the spinal cord very rarely following railway concussion. Nothing in the whole range of inquiry stands out more prominently than the fact that the lesions which become the subject of medico-legal inquiry, are met with only in a *few* isolated cases."

Page says,<sup>15</sup> "In fact, serious and undoubted derangement of the functions of the spinal cord as the result of simple concussion of the spine, is probably rare; whilst cases in which the symptoms of spinal shock do not appear for weeks or months after an accident, are *exceedingly* rare." He also remarks, "that there is no evidence that the victims of railway collisions, numbering thousands, have afforded a larger proportion of the degenerative conditions of the cord which have for years engaged the searching attention of pathologists, than those members of the community who have not suffered the same influences. There is no evidence that they have." *Bramwell*<sup>16</sup> says, "I think the chronic diseases of the cord claimed to be developed by railway collisions are infinitely more *rare* than has hitherto been supposed." *Reynolds* describes<sup>17</sup> "cases in which a patient has no intention to deceive, but really believes that he is the victim of serious organic disease. He is usually of a highly nervous temperament and often very active, mentally. His fixed belief *induces* functional disturbances, as twitching, muscular pain, excitable action of the heart, palpitation, exhaustion after slight exercise, and he becomes impressed with the idea that he is unable to do anything; that he is paralyzed and that he cannot sleep, awaking unrefreshed." Such cases I have often seen.

*Reynolds'* opinion and my own corresponds with that of Charcot and also of Grasset, who has described such cases:<sup>18</sup> "as hystero-traumatism or nervous affections sometimes resulting from wounds." *Knapp* says,<sup>19</sup> "Whether there is a

<sup>19</sup> *Lçons sur les maladies du système nerveux, par Charcot.* Paris.

true concussion of the spinal cord is still a matter of doubt. I mean a paraplegia following injury, where the cord has sustained no coarse mechanical lesion, where molecular changes in its finer nerve elements have occurred, giving rise to immediate and complete functional paralysis."

Although this evidence shows doubts as to the results often claimed as those of spinal concussion, it has been recently demonstrated that the spinal cord may be occasionally so shaken as to ultimately induce molecular changes in its structure without any injury to the canal, this being proved by post-mortem examination and the investigation of the minute structure of the cord under coloring, hardening and microscopical sections; but such cases are certainly very rare.

As muscular nutrition is dependent on a proper nerve supply, its deficiency will indicate such changes in the cord as atrophy, softening, etc., and Gower in his recent work says,<sup>60</sup> "Any destruction of the nerve cells will also cause degeneration of the motor fibres proceeding from those cells, with wasting of the muscles to which these motor fibres proceed." Hence, injury to the spinal cord should always be indicated by muscular atrophy in a more or less marked degree, and when no change is noted in the nutrition of the muscles, doubt may well exist in the mind of the expert as to there having been any concussion of the spinal cord.

A demonstration of the muscular development and power of a claimant may then well be made to a jury, in explanation of the condition of the plaintiff's nerves claimed to be impaired by the concussion. Gower also states that "Visceral control especially of the bladder and rectum (though the latter is sometimes under the immediate control of the branches of the sympathetic nerve), is also related to centres in the spinal cord, and although the action of the bladder and rectum can to some extent be controlled by the will of the patient, yet the latter cannot control the reflex processes when the volitional path in the cord is interrupted above the lumbar centre."

When the damage to the cord also involves the sensory tract, the claimant may be unconscious of the state of his bladder and the urine will dribble away. Pain in the spine, which is often spoken of by a patient, is no evidence of concussion of the cord, as it is occasionally present in organic disease of the cord, and more frequently in cases of disease of the meninges or bones.

Page regards this pain in the back, so often claimed as a symptom of concussion of the cord, as being due to the strain of the muscles or ligaments of the spinal articulations, and not necessarily indicative of cord injury. Gower says "softening of the cord is common; derangement of its functions few and rare. A severe concussion of

the cord may cause instant and grave damage usually by hæmorrhage, or it may cause no immediate effect and the symptoms appear at the end of a few days and progress rapidly or slowly." It is therefore apparent that in such cases, symptoms of injury to the cord should be found *soon* after the accident and not (as is sometimes claimed by lawyers prosecuting a claim) several months after the occurrence.

Hodges states: "It is characteristic of concussion of the spinal cord, that its phenomena are *immediate* though the recognition of them may not be equally prompt."

The development of an injury from spinal concussion should therefore be specially studied in reference to the *time* after the accident when the claimant first begins to complain. This time should be a few hours or days after the injury, and not weeks subsequently, when his mind, by dwelling on the accident and being posted as to the symptoms of successful awards made in other claims, has induced that emotional, hysterical or decidedly fraudulent condition of the body and mind which constitutes malingering.

#### POST-MORTEM EXAMINATIONS IN CONCUSSION OF THE SPINE.

The following cases illustrate the pathological conditions noted in well developed concussions of the spine, and prove that such an injury though rare, is possible:

In the *Canadian Medical and Surgical Journal* for Oct., 1884, p. 156, Dr. J. Campbell, of Seaforth, Ontario, states, "That serious and even fatal effects arising from injuries of the spinal cord even when it has not received any direct injury, is proved by a case reported by Dr. Edmunds in the current number (October, 1884) of the journal "*Brain*," where a soldier struck in the back by a bullet which entered three inches from the spine, immediately fell, was carried off the field, and was found to have lost complete control over both of his lower extremities, with paralysis of the bladder and rectum. Cystitis and a bed-sore over the sacrum supervened and he died five months after the injury. The autopsy showed that there was no fracture of the vertebræ; that the theca vertebralis was intact; but the spinal cord was found much atrophied and softened about the level of the wound. On hardening the cord in Müller's fluid, universal myelitis was noted, with softening for about two inches opposite the wound; this gradually passed downwards into sclerosis of the lateral and anterior pyramidal tracts and upwards with sclerosis of the posterior median columns. There was no indication of hæmorrhage, either internally or externally in the substance of the cord, and its surface was uninjured."<sup>61</sup>

A marked illustration of a similar pathological condition showing that degenerative changes in the cord do sometimes, though rarely, follow con-

<sup>60</sup> Manual of the Diseases of the Nervous System. By W. R. Gower M.D. American Edition Philadelphia 1888 p. 130 *et supra*.

cussion, has been kindly furnished me by my friend Dr. Arthur V. Meigs, of Philadelphia, one of the Attending Physicians of the Pennsylvania Hospital. As the details of the case, with its microscopical illustrations, have not yet been published by Dr. Meigs, I give his account of it from a letter recently sent me :<sup>22</sup>

A sailor, 35 years of age, was admitted into the Surgical Wards of the Pennsylvania Hospital August 20, 1888, and died September 15 of the same year.

*History.*—During a storm ten days before his admission to the Hospital, he was struck by a wave and dashed against the bulwarks, striking the back of his head and neck against the rail. On being picked up it was at once found that he had lost all sensation of power and motion from the clavicles downwards, and that he had retention of urine. When admitted to the Pennsylvania Hospital (ten days after the accident) he had a large bed-sore on his back. His temperature varied from 100° to 103°. Examination of his urine showed nothing abnormal, and there was no violence or signs of fracture or luxation of the vertebræ. He was treated on a water-bed; a poultice was applied to his chest because sonorous râles were heard on examination of his lungs, and iodide of potash was administered. The râles increased in his chest until the lungs were full and he became unable to expel the secretion; abdominal tympany supervened and he became comatose, dying apparently of heart failure. The autopsy showed that there was neither luxation nor fracture of the spine, and though the spinal cord was carefully examined at various points by the unaided eye, no sign of its diseased condition was noticed. The cord was then placed in Müller's liquid<sup>23</sup> for hardening and microscopical examination. After having been thus preserved in the fluid for a few weeks, the gross evidences of disease became very manifest and the histological appearances still more so; the lower part of the cervical swelling being almost disintegrated, there being at this point an almost complete transverse myelitis, the greater part of the tissue consisting of the so-called granule-cells with swollen and extended fibres; corpora amylacea and large nucleated cells that stained very red with carmine; whilst there was much space apparently empty, which had been probably filled with albuminoid material or liquid, for if this had not been the case the tissue would have collapsed instead of hardening in Müller's fluid. Above this region there was marked secondary degeneration, the section being taken only a short distance above the myelitis, though this was general in a slight

degree throughout this portion of the cord. But in a part of the posterior columns, it amounted to a complete destruction of the nerve fibres. Below the region of the myelitis there was descending degeneration of the lateral pyramidal tracts, this extending downwards into the lumbar region. These areas of degeneration were very evident to the naked eye after the cord had been in Müller's fluid, the degenerated part of the white substance of the cord having taken a yellow color, exactly similar in shade to that taken by the gray matter, while the portions of the white substance that remained healthy were of a greenish hue." My examination of some of the sections fully confirmed Dr. Meigs' description of the pathological changes.

That diseased molecular changes in the structure of the spinal cord have been occasionally seen without apparent mechanical injury, is shown in the following case, reported<sup>24</sup> by Dr. Wm. Hunt, of Philadelphia, "where a gentleman who traveled very frequently in railroad-cars, but never received any injuries as the cause of his disease, began to complain of pain in the posterior root of the neck. Paralysis, at first of the upper and subsequently of the lower extremities, was developed, and within a year he died, and the autopsy revealed spinal meningitis, with softening and destruction of the cord to the extent of 2½ inches in its brachial enlargement. As there was no other cause known, it seems as if 2½ inches of the spinal cord had been softened and atrophied without any mechanical cause;" yet if this man had received even a slight jar and presented such symptoms, his autopsy might have indicated "Concussion of the Spinal Cord." There are some persons who believe it possible to impair the functions of the cord, and even induce paralysis, from the jars created in the spine by constant travel; but if this were true there ought to be very many instances of it found in commercial travellers, none of whom are known to thus suffer. Nor is it true of such men as engine drivers on express trains, who are more exposed to jars on a locomotive than would be the case in a passenger car, and I am assured by an experienced General Superintendent of one of our largest railroads, that engine drivers do *not* show any evidence of concussion of the spinal cord after years of service on express trains. Constant travel as the cause of spinal degeneration is, therefore, not proven.

#### CONCLUSIONS.

1. Concussion of the spinal cord is no longer a matter of doubt, but may sometime occur as the result of various forms of violence, their being nothing peculiar in the application of the force to the body, as the result of derailment or collision of railroad trains.

<sup>22</sup> I am indebted to Dr. Campbell for a written account of this as I did not have access to the printed report in the Journal. The report was made to the Medical Association of Ontario and printed in their Transactions.

<sup>23</sup> M.S. dated April 26, 1889.

<sup>24</sup> Müller's liquid consists of 2 to 2.5 parts of potassium bi-chromate, 1 part of sodium sulphate, and 100 parts of water.

<sup>24</sup> "System of Medicine," by Pepper. Vol. 5, page 915. Philadelphia, 1886.

2. The pathological changes noted in the molecular structure of the cord as the result of shaking, jarring, or so-called concussion of the cord, when attended by paralytic symptoms, may be due to a hæmorrhagic effusion, or be shown post-mortem, in softening and localized or limited atrophy. In cases due to hæmorrhage, the symptoms may be improved by judicious treatment, and permanent disability prevented.

3. The possibility of preëxisting neurasthenia or hysteria or fraud on the part of a claimant, should be carefully noted in forming a *diagnosis* in these cases.

4. As the question of permanent disability justifying exemplary damages is frequently raised in claims of the kind alluded to, it should be recollected in forming a *prognosis* that numerous cases are reported of recovery or marked improvement in a few weeks, and one in three years even, after the occurrence of paralysis.<sup>55</sup>

5. No physician should go into court and swear that a plaintiff has had a concussion of the spinal cord, or of its nerves, unless he has proved the disturbance of the normal functions of the cord, as shown in sensation or motion or both, and that the symptoms appeared *soon* after the injury.

## THE MEDICO-LEGAL ASPECT OF CONCUSSION OF THE SPINE.

*Read in the Section of Surgery and Anatomy, at the Fortieth Annual Meeting of the American Medical Association, June 25, 1889.*

BY HERBERT JUDD, M.D.,  
OF GALESBURG, ILL.

The facts stated in this paper are drawn solely from my own experience as a surgeon—being cases resulting from or suggested to the patient by accidents; cases in which all objective signs of injury, if any ever existed, had passed away; cases in which the question of supposed or alleged concussion of the spine were under observation from a medico-legal aspect; cases in which compensation for personal injury was sought. In bringing this paper to your notice I do so with a feeling somewhat of duty. It is plainly evident to all thinking, practical surgeons that the question of the concussion of the spinal cord, if such a disease can exist, has become a matter of *business* interest—a business transaction in which the extent of the disease or injury is to be determined in the currency of the country. I say this, because of my experience during the last twenty years, I have found but two cases of alleged concussion of the spinal cord, except those resulting

from accidents caused by actual or constructive negligence of others, and where, if an injury existed, there was an opportunity to recover compensation in money. This is the history of all, or nearly all, the reported cases, and, as stated by Erichsen, "the consideration of these cases from a medico-legal point of view is a matter of the greatest importance by reason of the difficulties with which they are surrounded and the obscurity in which they are enveloped."

It is demanded by the honest business interests of the country, by cities, transportation, mining and manufacturing companies and by all employers of laborers, that the subject of spinal concussion receive the most thorough attention at our hands. If we do not expose the cheats and frauds, and protect the deserving claimant, who can do so? That cities and corporations are robbed of vast sums of money yearly by malingerers, aided by unscrupulous legal talent, and by ignorant or dishonest surgeons we all know to be true. This subject has reached this disagreeable status. A person can claim to be injured in a collision of trains, or by other accident, no objective symptoms or signs can be discovered, nor upon close examination found. Nevertheless, such person never fails to find abundant medical testimony, and the assistance of friends which with the required legal talent, will be sufficient to successfully prosecute a suit. Especially is this true when the defendant is a corporation. Such cases can be and are based upon, and carried to the end upon only a few vague subjective symptoms, every one of which depends alone upon the word of the claimant who seeks damages.

I make these statements, not as a partisan, not as a corporation surgeon, but assert them as truths determined by my own personal experiences in cases in which I have been interested as the attending physician from the choice of the patient, in some of which the patient hoped to secure my aid in collecting damages. In some of these cases I have been sorely tried, and, I confess, for a time deceived and misled, in trying to determine whether or not any injury to the spine existed. Some of these patients, where lapse of time had proved conclusively that they had received no injury, had always been considered good neighbors, fair citizens and reasonably honest men. How, then, can we account for such cases? Until the statutes of the various States were enacted, favorable to such claimants, and the laws of fellow servants practically abrogated, symptoms were perhaps seldom deliberately and purposely manufactured, but we all know that patients are apt to greatly exaggerate their complaints. This is no doubt done in many cases unconsciously. In cases of this kind, surgeons and physicians are very liable to be deceived and imposed upon, and made the tools of designing,

<sup>55</sup> Injuries to the Spine and Spinal Cord, by Herbert W. Page, F.R.C.S. Second Edition. London 1888 p. 263, who says: "Happily the record of cases which we have been able to collect is conclusive that recovery is usually very complete and the patient able to resume his occupation and carry on his business as well as he did before being injured."

<sup>56</sup> See also, Dana, New York Medical Record, November 21, 1884, page 617.

unscrupulous men, if not well schooled in reading character and determining motives. Definite opinions of imposture in many cases must be non-medical. We may reasonably suspect imposture where there is no organic disease, and where there is obvious motive or money consideration for deception. We might perhaps remain quiet and permit our patients and neighbors to rob corporations on the ground that it does not concern us, just as we take no active part in enforcing the criminal laws of our States for the reason that we are not charged with that duty. But when we find such an increase in imaginary diseases, and find members of our own profession deceived, or deliberately aiding these malingerers, it is time for us to protest as a class. But this is not all. The facility with which damages are collected from corporations is breeding a large class of dishonest persons. It is infectious; men grow more and more to disregard the obligation of an oath. The government itself is a victim; patriotism and sentiment aid. All this tends to demoralize society, and to wrong the honest claimants for damages or for pensions.

Railroad attorneys inform me that it is now their custom to take the names and address of every passenger on a train that has met with any serious accident, because their experience is that at least one-half of the passengers who receive no injury will, before claims are barred by statutes of limitation, bring suit, and claim concussion of the spinal cord. They learn that those who receive trifling injuries recover large sums, and then comes the temptation to extort money, because they ran the same risk as those who were injured, and they quiet their consciences by assuming that although uninjured the railroad company ought to be made to pay for putting them in jeopardy. In some of these cases there may have been trivial injury, and then the conscience of the patient is somewhat relieved and he finds excuse for deception, and the temptation is so great that few seem to have sufficient moral courage to resist. Many a man who had previously had no public stain upon his character has yielded to the great temptation. Can we not do something to save these men from themselves, and to save our professional brethren from temptation, and from becoming the victims of unscrupulous malingerers?

It is no pleasant task for me to bring cases before you, but in doing so I cannot be charged with being partisan, or with having any desire to prevent any honest claimant from securing just and full compensation for all actual injuries sustained through the fault or misconduct of another. Several years ago I withdrew from all connection with the railroad company I had for some years been connected with.

The knowledge I have sought and which I think I have gained in connection with cases of

alleged concussion of the spinal cord and other cases of malingering, forbids me from remaining silent, especially when I see that the tendency of such pretended injuries or disease is to lower the standard of the medical profession, and to cause the people who see the results of these cases after the money consideration has been paid, to lose faith in the honesty and integrity, or in the skill and knowledge of physicians. I append statements of a few cases that have come under my observations: cases followed by me carefully after judgments were paid or claims settled, and in which recovery was complete in a surprisingly short space of time, without the aid of surgeons or physicians. Such cases have of recent years become so common that the medical profession is brought into ridicule, and it is not rare that intelligent men of a community assail us with the jocular information that railroad officials with no knowledge of medicine or surgery, succeed in producing speedy and permanent cures with money, where our skill and care produced no improvement in the patient.

It is said, and it is probably true, that more people are injured every year by riding in carriages and by farm work than by railroads. Yet injuries that are pure accidents, or injuries where a corporation of some character is not at fault, never result in concussion of the spinal cord. And where injuries occur through accident, for which no liability can attach, we find no malingerers.

*Cases 1 and 2.*—May 10, 1889, I was called to see Mr. and Mrs. C. G., aged respectively 62 and 63 years. They had been riding in a spring wagon; the horses were frightened by cars and ran away, throwing the occupants out. There were no visible wounds or fractures, but the patients were suffering from shock. I surrounded them with blankets and jugs of hot water, and after four hours of rest, sent them to their home five miles distant. These people were disciples of Hahnemann, and the next day sent for their family physician, and in a short time concussion of the spine was alleged in both cases. Damages were paid. The man is still living and in average health for one of so great an age. The woman was alive and in good health three years ago.

*Case 3.*—E. H. H. was walking on a sidewalk and fell into a pit eighteen inches deep, extending from a basement window. I saw him a few days afterwards. His thumb was swollen, and that was the sole objective symptom. The patient at once talked of the amount of damages he could recover, and complained of his back. This man was a hanger-on about the courts, and had some ideas as to how to proceed, and his subjective symptoms were in the line of his desire to recover a judgment. This case was properly attended by a skilled surgeon and physician, a man who stood

above reproach. Through his care and *warning* the spine recovered, although the patient's friends asserted positively that he suffered severely from concussion of the spinal cord, and other alleged doctors were called to examine the patient. The physician in charge became disgusted with the malingering and abandoned the case, and through fear of his testimony, no doubt, the concussion theory was abandoned, and the thumb grew worse. The thumb and hand were firmly bandaged, until there appeared to be permanent contraction and disfigurement. Suit was brought against the city, and good legal talent was employed, for lawyers as well as doctors can be found to work in such cases for a consideration. The city was mulcted several thousand dollars, although competent and reputable physicians testified that the sprained thumb would have recovered in a short time without treatment, if it had been left alone and not bound and poulticed. Within one month after the judgment was paid, the man, to the disgust of his friends, was at work on his bench as any shoemaker should be, and the recovery was complete. This case would have gone through the courts as an aristocratic case of concussion, instead of a plebian case of a sore thumb, had not the honorable physician who first attended the case stood in the way.

*Case 4.*—Concussion of the spine—so-called and treated by two reputable surgeons. Liability conceded by a railroad company. Damages estimated on the basis of permanent injury and the presumption that the man could never walk again. A complete book case. A large sum of money was paid, and a few days thereafter the man *walked* to the cars in the night time and left the State. The case was as follows: The claimant was an engineer. In making a rapid switch a rail was broken, and the engine left the track and tipped over. The fireman was killed and the engineer thrown out and stunned and bruised. His family physician was called, and he in turn called a surgeon, who justly ranks high. There were no objective symptoms. The man was apparently scared. There had been no shock. The case gradually grew to be a case of concussion of the spine, a "book case." In justice to my esteemed medical brothers who attended the case, I will say, that under the circumstances, and with death resulting to the companion of the patient, other surgeons would have been likely at that date to have been deceived. I rejoice at my escape from this case, for I sadly fear that with the experience I then had I should have believed the patient's statement and symptoms related. The recovery in this case was complete, and the man last heard from, some five years after the accident, was in robust health.

*Case 5.*—F. P., age 18, brakeman, habits questionable, health undermined, inclined to consumption, was on top of box car in a train under

way. Head end collision. P. jumped from train and fell some distance from the track; when found he lay in a depression in the ground on his back, with his back across a railroad tie. He was brought a distance of 23 miles to his home. He was met at the station on his arrival by the writer, four hours after the accident, and was carried home on a hand stretcher. When met at the station reaction was progressing naturally. He had received a great shock. Two hours after seeing the patient at the station, I again saw him, and being the attending physician of his father's family, and the residence being a short distance from my office, I saw him often. In this I made a mistake. There were no objective symptoms. The subjective symptoms were pain in the back over the dorsal vertebra. My directions in the first instance were to keep him warm and let him alone until I again called. The pain being apparently so great, I called to my assistance a very painstaking physician. We carefully examined the patient and found curvature of the spine, bold and distinct. We abandoned further examination at that time and regarded the case as hopeless. To our great surprise, however, during a later visit the same day we found reaction fully established, with no complaint of pain. We then again examined the back. The deformity of the spine was decidedly marked, but there was no tenderness upon pressure. We made no further examination for several days, and in the meantime I described to his mother the condition of the spine as we had observed it, and our fears of a serious injury and fatal result. This was my second mistake in this case. The information I communicated to the mother, to my surprise, did not greatly disturb her, and here my suspicions were aroused. I had long been her attending physician, and the patient was her son, and yet my opinion of her son's condition was received quite calmly. From this time on the curvature of the spine became in the minds of the family more pronounced, and the money question began to be considered. To protect myself and guard against an outrage being committed, and for the purpose of saving the reputation of the family I had so long attended, I procured skilled help and made a correct plaster cast of the whole back. I had seen lawyer's tracks. Secret meetings had been held in the back parlor, as was reported to me. I was quietly interviewed and informed that the case was all clear if I was all right. The whole family asserted to me that prior to the accident no deformity of the back had existed. I was in trouble, and consulted with the physician whom I had called in consultation, and we took such steps as we could to save ourselves from being either parties to a contemplated robbery, or from wronging the family that had trusted me. A brother of the patient, a bright boy, had some years before been my office boy. He was absent

from home at the time of the accident. When he returned he told me that his brother's back had been that way since he was a little fellow.

I devoted my labors after this to getting my patient out of bed and on to his feet, but he insisted upon the necessity of crutches. I could do no more; the spine grew worse; suit was brought because a fair and, in truth, a generous offer made by the railroad company was indignantly rejected. Foreign surgeons were called to examine the patient preparatory to testifying. I knew the case was one of malingering, and so informed the attorney of the railroad company. The surgeons who had no knowledge of the case, except as related to them by the patient and family, would readily have testified to the permanent injury and that the accident was the cause. When the case was set for trial I was so beset with difficulties that I was compelled to exhibit the cast of the back, and to urge that surgeons for the railroad company might make an examination. This was done. It is sufficient to say that Dr. J. Adams Allen cured the case within the half hour before Court convened. So thorough was the cure that a reasonable sum for the actual injury, less than the amount previously offered, was greedily accepted. On the evening of the same day the crutches were abandoned, and the afflicted spine was supporting the body of an intoxicated man.

This, gentlemen, is a true history of a case that occurred in a family that had my confidence and respect. It cost me many gray hairs.

*Case 6.*—A middle-aged man of nervous temperament, of health feeble for years, tripped and fell from a defective sidewalk. Accident happened in front of his own house. He immediately took to his bed. A reputable physician of long experience in general practice was called. The patient remained in bed—as was supposed—for some months, when suit against the City was brought, based upon permanent injury to the back, on account of spinal concussion. The case was on trial with the plaintiff in bed, unable to attend, as was alleged, when the writer and another physician were solicited by the plaintiff's attorney, who had faith in the honesty of the case, in order to further the ends of justice, to go and examine the plaintiff, and testify to his crippled condition. We found the man in bed, and evidently prepared for our coming. Not the slightest objective symptom could be found, but the subjective symptoms were perfectly in accord with all the recorded book cases. With careful effort we got the man out of bed. The imperfect walk, the peculiarity of gait and carriage of body, were just what a student would expect to find after having freshly read these cases and never before having seen one.

I am not naturally suspicious. I want to have faith in mankind, I want to be just, but there were many things which I cannot fully explain; the manner of the man, his guarded language, his

suspicious glances, that caused me to suspect that we were being misled, and being entangled in the trap set by designing lawyers, or credulous and ignorant physicians. I informed the plaintiff's attorney of my suspicion, which after some tests had become a conviction, of the plaintiff's dishonesty in this case. I was nevertheless called to testify, because, as I was informed, my silence after it was known that I had made the examination, would be more damaging than my negative testimony. I testified substantially that I had no positive means of knowing or satisfying any one else that the man was simulating all his symptoms, that I had never before had cause to suspect him of dishonest practices, that there were no objective symptoms or signs of injury, that the whole case depended upon the symptoms which could be simulated, and upon the statements of the patient, and upon these alone. I was asked by the attorney for the City to answer that had the accident happened within his own dooryard, or where no one would have been liable, would the symptoms have been the same? I answered, "No, I certainly think not." This testimony was, however, "ruled out" by the Court. The surgeon who made the examination with me corroborated my opinion. I did not hear the testimony of the attending physician, but was informed that he thought it improbable that all the symptoms could be manufactured; that in all such cases the physician had to rely upon the statements of the patient, and that he could not be properly treated if symptoms stated were ignored, etc. Judgment was given in favor of the cripple, and the money paid. A few weeks afterwards I was much surprised—or would have been had I believed the man's story—to see this same plaintiff riding about the city; and about five months after the trial I ought to have been again surprised beyond belief, I suppose, to see this same man, permanently crippled from concussion of the spine, put a heavy stove into a lumber wagon. To be certain that I was not mistaken in the person I went to him and shook hands with him. He is not now a strong man, and was not before his fall on the sidewalk, but, knowing him well both before and after the fall, I can state positively that he is in better health and in better physical condition than before the accident. It is certainly very unpleasant for me to record this case. I have no personal ill will against the man. He was the victim of his cupidity, and only followed the precedent set by many other "honorable men." I was recently called to his fireside to treat a member of his family.

*Case 7.*—A young married man, jeweler by trade, had occasion to go hurriedly to a railroad station. Unknown to this man, as he claimed, the station platform had been partially removed for repairs. The sidewalk, which was in place, had formerly terminated in the platform. The

removal of the platform left the end of the sidewalk about 14 inches above the level ground. The man stepped off the end of the walk, and fell to the ground. This is the history of the accident given by the patient—no one else witnessed it. He got up, went into the telegraph office, sent a message and returned home. The case was brought to my knowledge some weeks afterwards by the attorney of the railroad company, who desired me to examine the man together with the doctor in charge. At my suggestion, permission was granted by the attorney for the claimant to call a third physician. I called Dr. H., an old practitioner, and a man beyond reproach professionally and otherwise. I found the history of the case as stated above, and that permanent injury was claimed; that suit had been brought in one County and that the attorney who brought the suit had abandoned the case because he believed the man dishonest in his pretenses of injury. This put us on the watch and compelled a critical examination. The desertion of one attorney did not deter the claimant, nor seriously discourage him. Lawyers are no more virtuous than physicians, and a speculative lawyer was soon found ready to take the case, and a new suit was brought in another County. The physician who had been treating the case was employed specially because of a reputation he had previously acquired as an expert witness for the claimants in spinal concussion suits. The attorneys representing both plaintiff and defendant were present. This was a mistake, and was chargeable to me. No proper or satisfactory examination could be made under the circumstances. The case presented in all its aspects the appearance of chronic disease, or permanent injury; the general appearance of the patient was bad, suggesting rheumatism. Aside from this there were no objective symptoms. I stated that if his present condition was due to the fall, he was certainly injured. He finally admitted, because it was susceptible of proof, that he had repeatedly suffered from rheumatism for some years. It did not seem possible to Dr. H. and myself that this person could be in his present condition from any injury a person could sustain from the accident related. The doctor in charge of the patient and his claim stated that it was a case of permanent injury to the back. The case came to trial, concussion of the spinal cord was the plea. It was shown by his own testimony how much he had suffered and was suffering. The doctor in charge either dishonestly or ignorantly corroborated his patient, although admitting that no medicine had been used. Some of the most candid and intelligent surgeons of the State of Illinois, all members of this Association, were called by the railroad company as witnesses. The track gone over in this case was the same old beaten path, the only road possible to travel, that is the man's own word and

subjective symptoms. Book cases were rehearsed to the jury of concussion of the spinal cord by a professor of the Physio-Medical College—formerly of Cincinnati—the pale face of the rheumatic patient, the prejudice of a jury in favor of a claimant and against a corporation, succeeded, and damages were awarded to a large sum. After payment of the judgment, the patient recovered from all trouble, except rheumatism, so rapidly as to abash and disgust the innocent jurors and sympathizing friends, and finally taunts and charges of dishonesty became so numerous that the claimant felt it safer to emigrate from the County, and the doctor, who was also a druggist, has removed, but before going, instead of pleading ignorance to the discredit of his skill as a physician, admitted that it was a little scheme to get even with a soulless corporation. The claimant had not sustained the slightest injury; indeed, it is believed by the citizens of the village that he did not even fall from the sidewalk.

I will not burden you with reference to any further cases. It would be but a repetition. You have no doubt had similar cases. I have been unfortunate, it may be, in having a number of other cases brought to my knowledge, a number in excess of what might seem usual; but I have no doubt no greater number or kind, as regards the subject of concussion of the spinal cord considered in its medico-legal aspect, than have come under the observation, in the practice of a large number of those present.

If a young man can begin life with the truth visibly laid before him, and be warned of the snares set for him, and be helped to avoid deception, some of the obstacles to his honorable fame may be removed, and his path be made easier. If the young men in the profession could realize that cheats and frauds are not rare, much good might be accomplished and less harm done.

I must certainly question if there be such a disorder or injury as concussion of the spinal cord, as some of the books tell us, or describe it. I have certainly been a hard worker after the truth in this matter, and have not exaggerated the cases I have reported, and have withheld reports of other now notorious cases of pure fraud and malingering, in which honest but credulous physicians were misled, deceived, and their reputations injured.

I trust that members of the profession more skilled with the pen than I am, more capable of expressing their ideas to others, will give the subject careful study, and give their views to the public. To learn the truth these cases must be followed and observed, not only before judgments are paid, but for months afterwards. I would be happier if I could be convinced or could convince myself that I have been mistaken in all these cases, and that the remarkable cures effected apparently by juries, were really cures effected by

the kindness of Divine Providence, or by the labors of Christian Scientists.

If in my awkward way, and by my crude language I shall succeed in creating enough interest to cause others to be on their guard and to study this class of cases when damage suits are brought, I shall be content.

#### DISCUSSION.

DR. WM. BRODIE, of Detroit, Mich., cited two cases, in one of which his testimony was for the plaintiff; in the other, against. The jury gave the plaintiff heavy damages in both cases. Conclusions: Immediately after a man is hurt the railroad surgeon should advise the company to settle, for if injury of spinal cord has occurred the patient will continue to give evidence of his injury; and if not, the damages received from the company will prove immediate cure, and thus demonstrate that no injury had taken place. Juries cannot be made to see the difference. It is only necessary that the defence be a rich corporation. He also cited a case at Cobourg, Ontario, wherein the G. T. R. W. was defendant. The injured man recovered in less than ten days after the verdict in his favor and was married. Has been in perfect health since, although he played paralyzed for near two years, with loss of sensation in his extremities. Such perfect control did he have that neither needles nor electricity could make any observable impression upon him when applied even without his direct knowledge. Of course he was aware that he was being put to some test, and his will controlled.

DR. B. A. WATSON, of Jersey City, N. J.: Spinal concussions are not so frequent as would seem from court decisions. I have observed as the most frequent injuries following railroad accidents: 1. Hæmorrhagic infarction in lungs. 2. Lacerations of liver, spleen, lungs, or kidneys. 3. Rupture of blood vessels and bladder.

DR. CHARLES B. PENROSE, of Philadelphia, said: I think that we are all in accord with the principles expressed in the papers which we have heard to-day, and we protest against the robbery of corporations and the consequent discredit brought on our profession by supposed victims of spinal concussion.

The rarity of any serious injury to the spinal cord, unaccompanied by injury to, or lesion of, the surrounding bony or ligamentous structures, is shown by the records of large surgical hospitals, where simple spinal concussion analogous to transient cerebral concussion is exceedingly rare, if not altogether unknown.

In the Pennsylvania Hospital, where there are treated yearly about 700 cases of fracture, luxation, sprain and contusion of sufficient gravity to demand in-door hospital treatment, simple spinal concussion is one of the rarest conditions met with. And yet these injuries are produced by

falls, blows and collisions, which must cause more or less jarring of the whole body, besides the local fracture or contusion, or sprain for which the patient is admitted.

I am familiar with the details, and have examined the specimens of the very interesting case of spinal concussion referred to by Prof. Smith, as that of a sailor admitted to the Pennsylvania Hospital, who had been thrown violently upon the nape of his neck. The autopsy was made most carefully with the special object in view of determining the existence of any injury to the bones or ligaments of the spinal column, as in such cases there is always a probability that an unrecognized fracture is present, or that dislocation has taken place and been immediately reduced, so that no deformity is afterwards apparent. But in this man no fracture of bone or laceration of ligaments was found. Nor does it appear, from the nature of the accident, that any sharp flexure had occurred and produced undue tension upon the cord; nor was there any indication of hæmorrhage from the vessels of the cord or of the membranes. It seems, therefore, to be a simple case of injury or concussion and subsequent degeneration of the cord, produced by direct violence without any fracture or laceration of the surrounding structures.

Women at the menopause are frequent malingerers of spinal concussion, or spinal shock, and their nervous symptoms sometimes really deceive themselves and friends, being falsely attributed to some more or less severe injury coincident with the real physiological cause of their trouble.

I have examined two such cases, where, in court, trifling injuries were affirmed to have caused spinal concussion, and were held responsible for all the hysteroneuroses of the menopause. In one case the plaintiff was non-suited, in the other a compromise was effected. In both women all symptoms of spinal concussion probably disappeared as soon as the menopause was over.

An important point which Prof. Smith has mentioned, is the impossibility of giving a certain prognosis with regard to permanent disability after spinal injury.

An exceedingly interesting case, where recovery of muscular power occurred after prolonged paralysis from a very severe spinal injury and probable fracture, came under my observation about two years ago. The man had been a soldier, and in the battle of Cross-Keys had been struck by a bullet on the cartridge belt and had fallen backward from a height, upon the buttocks. He was not wounded by the bullet; but his back was so injured by the fall that he was immediately paralyzed and he was obliged to lay for three years on a water-bed, with paralysis of the legs and incontinence of urine and feces.

He afterwards regained muscular power suffi-

ciently to lead the laborious life of a peddler, tramping, with his pack for twenty years subsequently, through Pennsylvania and New York. The only mark of injury now apparent is a slight prominence of the lower dorsal vertebra. He has never recovered control over the bladder and rectum, or sensation in the skin of the buttocks on the posterior aspect of the thighs.

DR. J. H. MURPHY, of St. Paul, Minn., said: Erichsen has cost the railroads thousands of dollars. He cited several cases of malingering.

DR. WM. H. PANCOAST, of Philadelphia, said: The question under discussion has two heads. First, is there such an injury as concussion of the spine, and are there malingerers who assume the symptoms. That there can be cases of concussion of the spine followed by serious consequences, I firmly believe, for I have seen them. I have seen cases where a violent concussion in a railway accident has so affected the contents of the spinal canal as to cause effusions, or such alterations of the membranes of the cord or of the cord itself, as to be followed by paralysis more or less complete. Many members of this Section of Surgery and Anatomy must, in the course of their lives, from mis-steps or other accidents, have recognized the force and painful effects of concussion. I have within the past few weeks been engaged in a medico-legal case, where a delicate lady, the wife of a physician engaged in a large and active practice, was thrown from a carriage in which they were both driving. A careless coachman driving a heavier carriage ran into them, and the collision threw her to the ground and against a wheel, with such violence that she became insensible. She has remained an invalid ever since, with marked symptoms of paralysis on one side. In neither of these cases was there hysteria or malingering.

There are malingerers, and we must be on our guard against them, and I have such faith in the honor of the members of our regular profession as a class, that I do not believe they would be parties to such a deception. I have been called as an expert in several such cases, and have sometimes settled the medico-legal questions in my office to the satisfaction of both sides. I feel assured that this learned body recognizes the existence of such an injury as concussion of the spine, and also that while the great railroads who do so much for the benefit of the country, should be protected from suits inspired by fraud and ignorance, that the great public should also have protection. I think that if corporations would give fair compensation for injuries received at their hands, through accident or the carelessness of their employes, and not insist that such injury should be proved to be permanent, that a cause exciting to fraud or malingering will be removed.

I give credit to the corporation surgeons of de-

siring to be honest, and giving a truthful scientific diagnosis from their standpoint; then why should not we also recognize the statements of the surgeon of the injured, as being inspired by the same motive, even if some one may occasionally be deceived by an ingenious and artful malingerer.

From my experience I think that very many railway injuries can be satisfactory adjudicated and the sufferers properly compensated by the judicious surgeon acting as mediator between the opposing lawyers, to the honorable satisfaction of both parties.

## TWO CASES OF TUBERCULAR OSTEO-MYELITIS OF TIBIA.

*Read before the North Texas Medical Association, June 12, 1889.*

BY J. T. JELKS, M.D.,  
OF HOT SPRINGS, ARK.

PROFESSOR OF SURGICAL DISEASES OF GENITO-URINARY ORGANS  
IN COLLEGE OF PHYSICIANS AND SURGEONS,  
CHICAGO, ILL.

*Case 1.*—In the Spring of 1888, Mr. —, æt. 40, consulted me for great and constant pain in the left tibia. I found him in a hovel, poorly ventilated, poorly warmed, and poorly lighted. The odor in the room was simply unbearable, but with burning tar in the room I examined the patient as best I could. Found him greatly emaciated, with large ulcer on left leg, several inches in length, with the presence of pieces of dead bone. He was being cared for by some of the charitable ladies of the place and consented to an operation. Assisted by Drs. Thompson and Gebhart, I proceeded to operate. After the anæsthetic was given I washed and scrubbed his leg with soap and water, then with solution of bichloride of mercury, 1:1000; wrapped his feet with towels wrung out of the bichloride solution, and also covered his body with antiseptic towels. An Esmarch bandage was applied above the knee-joint—about 6 inches—to make a bloodless operation. I then proceeded to cut down to the tibia, making an incision from near the insertion of the tendon of the patella to within a few inches of the ankle-joint. Peeled the periosteum back on both sides of the line of the incision, and then with mallet and chisels I proceeded to remove the anterior surface of the bone, finding the focus of the disease not far from the head of the tibia. I continued the use of the chisels and mallet until I thought all the abnormal material was removed, and when through I had a trough six inches or more long, half inch wide and half inch deep in some places. It was now scraped out with the sharp spoon of Simon, irrigated with solution of sublimate 1:1000. Again irrigated with solution of sublimate 1:500, and when this was through with a quantity of 1:5000 solution was used to wash out the stronger liquid. The operation by being bloodless was

made more thorough, because I could inspect every crevice and corner of the large trough.

A Schede's dressing was applied—that is, the cavity was sprinkled with powdered iodoform, the skin stitched together where it would meet, and over the line of incision a strip of antiseptic oiled silk was placed, overlapping the incision one inch on each side and about the same at each end; over this was placed a strip of iodoform gauze, then a thick layer of sublimated cotton, and over that several layers of sublimated bandage, tightly applied; over all a protective of oiled silk, previously soaked in sublimate solution. When all this was done the constrictor was loosened, and the cavity I had made allowed to fill with pure blood, the leg being held as near vertical as we could get it. He had no fever from the operation. The leg was dressed in one week and found almost healed by the organization of the blood clot. In six weeks he was well and upon the streets.

*Case 2.*—Mrs. H., æt 30, widow, consulted me for enlargement of left leg, with two ulcers near the upper extremity of tibia. Constant pain in leg, so much so that she had resorted to frequent use of morphia to relieve it. One of the ulcers opened down on the tibia. I proposed opening the bone and turning out the diseased mass. She consented, and I asked Drs. Haffner and Thompson to assist me in the work. After the use of the antiseptic precautions detailed in Case No. 1, I proceeded to cut down on the tibia in the middle line, turning back the periosteum on each side of the line of incision. This was not very readily done at the upper part of the wound, a previous operation, similar to the one I was doing, having been performed on her in Detroit, Mich. This operation was rendered bloodless by the use of a constrictor about the middle of the thigh, and hence in the use of the chisels I could follow the diseased tissue wherever it went. I chiseled away until I had a trough of the tibia leaving its sides and bottom. This was well curetted with a sharp spoon to remove any shreds of diseased material left, its entire removal being absolutely essential to success. This was rendered aseptic by use of sublimate solution 1-500, and then 1-1000; finally it was irrigated by solution 1-5000, and a Schede's dressing applied. Constrictor was now removed and leg suspended in upright position until the blood clot could form, when it was let down on the bed. Few hours afterwards blood was noticed oozing from the bandage near the ankle-joint. A rubber bandage was tightly applied for two or three hours and then removed. When the hæmorrhage had ceased the wet spots on the bandage were sprinkled with iodoform, and a fresh antiseptic roller bandage applied.

This dressing was taken off at end of ten days, and not a drop of pus was found, but the upper

third of the cavity in the tibia was empty, lower two-thirds filled with well organized clot, skin united over it so that the line of union was scarcely perceptible. The bandage was not applied tightly enough to prevent the loss of part of the blood clot, hence the empty third at the upper part of the wound. I tried to persuade her to let me fill this cavity with blood from her arm but she would not consent. About once in seven or ten days this cavity was filled with iodoform gauze, and it granulated until healing took place requiring three months. Had not the blood clot been lost the entire cavity would have been healed in a few weeks.

When another opportunity offers to make this operation I shall utilize the decalcified bone chips of Senn—that is, I'll fill the cavity with these chips and allow the blood to cement them together, using the Schede's dressing as above described.

Tuberculosis of bone is a subject that has not been understood until the last few years. Formerly, caries, necrosis, and tumor albus were the diseases we had to contend with, when the bones were involved. Thanks to the labors of Koch, Volkmann, and others we now know that what we formerly regarded as diseases are but the results of disease. Dropsy was once a terrible disease, and is so regarded to day by the laity and some of the profession. We know it only as a symptom. So with caries, necrosis, and tumor albus. They are but the results of inflammation of the bone, or rather of the bony envelope—the periosteum, endosteum, or medullary matter. Practically, inflammation of bone means inflammation of these substances; they are practically one. The bony material itself is not inflamed, but the endosteum, or periosteum, swelling, the resulting pressure cuts off the blood supply of the bone, and caries or necrosis is a result.

The causes of bone inflammation may be set down as trauma, cold, and fever. Upon this trauma we have engrafted an infection with the microbes of pus, tuberculosis, syphilis, rheumatism, or gout. The pus microbes, the staphylococcus aureus or albus, or the streptococcus pyogenes, are very vigorous and active and produce a very violent inflammation; whereas the bacillus tuberculosis is a slow growing coccus—it is not a pus producing coccus—and hence its effects are slower in manifesting themselves, and when only the bacillus tuberculosis is present in a joint or bone, only granulation tissue is formed. It may be said also that the bacillus of syphilis and rheumatism are not pus producing bacilli, and that their effects are slower in manifestation, and hence chronic. It follows that the acute bone inflammations are produced by the pus microbes, and the chronic inflammations by either the bacillus of tuberculosis, rheumatism, or syphi-

ilis. Ninety-two per cent. of these inflammations of bone are so produced, leaving 8 per cent. for the pus microbes. Volkman, the greatest living authority on tuberculosis, says that 90 per cent. of the cases of caries are tubercular in their origin. When the trauma is slight the resulting bone inflammation is tubercular; when the injury is severe the inflammation following it is produced by the pus microbes. If the skin is not broken whence comes the microbes? We may say that they are floating in the blood current at all times, and, thanks to the leucocytes are being constantly destroyed, but when an injury results the effusion of leucocytes outside of the blood vessels renders them inactive, and a fine culture fluid is produced in which these microbes of disease have an opportunity to develop. If the injury is slight the inflammation resulting is tubercular or rheumatic; if severe, the pus microbes take possession of the field.

## MEDICAL PROGRESS.

ON INJECTIONS OF TESTICULAR LIQUID.—In the Société de Biologie de Paris M. Variot reported three experiments which had been made to ascertain the physiological action of fresh testicular liquid injected subcutaneously, after the manner of Brown-Séquard. The liquid used was obtained by crushing and triturating the testicles of a rabbit or of a guinea-pig in 10 cubic centimetres of distilled water. After separating this liquid from the residual pulp by simple decantation two Pravaz syringes of it were injected under the skin of the abdomen at a dose, the injections being repeated every forty-eight hours.

Variot operated on three men, of 25, 56, and 68 years, respectively, who were much debilitated from various causes. The effects produced in these three cases were satisfactory from the first, and continued so after subsequent injections. Sixteen injections were made in all. No harmful symptoms requiring any attention were noticed. The injections proved painful but harmless. The pain following the injection is considerable for several hours, it is even accompanied by a general feeling of uneasiness, but not by fever. The first injections are especially painful, the subsequent ones much less so. The positive effects (which were the same in the three men, the nature of the substance injected not being known to them) were as follows: a general state of nervous excitement, an increase of muscular strength, regulation of the functions of the digestive channel, and some cerebral excitement. An increase of virility was found in two of the three cases.

Variot is unable to answer the question: whether these phenomena were an effect suggested merely by the operation, or whether they were

actually due to the action of the liquid, as claimed by Brown-Séquard. The number of experiments is as yet too small.

Brown-Séquard claims that the conditions under which Variot made the experiments prove that there was no imaginary effect in these cases, but that the liquid really possesses the properties that he ascribes to it.

Brown-Séquard also made experiments with liquid obtained from other glands, and proved that a liquid obtained by trituration of the lungs contained a toxic substance. Liquids obtained from trituration of the liver and spleen had no effect whatever upon the animals treated with them.—*La Semaine Médicale*, No. 27, 1889.

ON THE ETIOLOGY OF PERICARDITIS.—In the bacteriological examination of three cases of pericarditis G. BANTI (*Deutsche Medicinische Wochenschrift*, No. 44, 1888) found, in the first case, no microorganisms at all in the fibrinous exudate, for which reason he considered that an example of non-infectious pericarditis. It was the case of a man 48 years old who had been suffering for years from a chronic nephritis, and had died during an attack of uræmia, symptoms of pericarditis having appeared a week before death. The author thinks that here pericarditis was ascribable to the kidney disease, and that its cause might be of a chemical character, or might be looked for in the uræmic attack, as it is known that acute inflammations are often complications of acute uræmic attacks.

Two other cases of pericarditis belonged to the group of infectious pericarditis and developed in consequence of fibrinous pneumonia. In the first of these cases the diplococcus pneumoniae was found in the pericarditic exudate, as expression of a secondary localization of the latter; in the second case the pericarditis appeared as a mixed infection caused by the staphylococcus aureus and albus. In this latter case the inflammation probably spread directly from the pleura to the pericardium, as there existed at the same time an extensive pleuritis, and the staphylococci were also found in the pleural exudate.

Regarding the first case the author supposes that the pericarditis was of hæmatogenous origin, and to prove this he tried to produce, with the diplococcus pneumoniae, pericarditis in animals. For this purpose he created an artificial pericarditis by injecting oil of turpentine into the pericardium, or by cauterizing the latter, and then injected pneumococci under the skin. Numerous capsulated cocci were subsequently found in the pericarditic exudate thus obtained. This pericarditis was most easily produced if from twenty-four to forty-eight hours were allowed to elapse between the injury to the pericardium and the injection of the pneumococci, in which case always an isolated inflammation of the pericardium

was found which did not extend to the pleura, the peritoneum or the mediastinum.

These experiments show that a hæmatogenous pericarditis may be produced in animals by means of the diplococcus pneumoniæ.—*Centralblatt für Klinische Medizin*, No. 20, 1889.

ON PULSATING PLEURISY.—MILLARD communicates the case of a man, 36 years of age, who was taken, in May, 1887, with pleurisy of the left side, which soon became complicated with pneumothorax. Nevertheless he improved, and could resume his occupation, until, in December, 1887, after a run, he was attacked by a sudden dyspnœa, with evident return of the symptoms of pneumothorax. In July, 1888, a tumor appeared on his back, to the left of the spinal column, on a level with the last ribs, which grew rapidly and soon pulsated synchronously with the heart. August 10 an incision was made into the thorax and  $3\frac{1}{2}$  litres of pus were extracted. The tumor fell and the pulsations ceased immediately. From August 28th to September 22d, during Millard's absence, five more incisions were made, and from 1,300 to 1,500 gr. of pus extracted each time, each operation being followed by the injection of a dose (which was then gradually increased from 80 to 115 gr.) of tincture of iodine. These operations were well borne. November 6th a puncture was made, with successful results, but the next morning all the symptoms of pneumothorax had reappeared. Then Dr. Peyrot performed pleurotomy. The ninth rib was resected for 3 centimetres, and again about 3 litres of pus were removed; rinsings with iodized and alcoholized water were made repeatedly, as often as four times a day, but hectic fever and diarrhœa continued, and November 27th the patient died. An autopsy was not made. Millard thinks that Fériol will be inclined to cite this case in support of his theory, inasmuch as the patient, before showing the symptoms of pulsating empyema, had had pneumothorax twice; he (Millard) is of the opinion, however, that experiments will be necessary to arrive at a true explanation of pulsating pleurisy.—*La Semaine Médicale*, No. 27, 1889.

TREATMENT OF DIABETES.—In an article by ALBERT ROBIN on this subject the following points are discussed: 1. The modifications which the laws of exchange undergo in diseases, explain the pathogeny of the latter and become the source of certain therapeutic indications. The knowledge of the effects upon normal exchanges produced by a drug renders it possible to foresee its real therapeutical application. There is reason for a revision, from this double standpoint, of the physiology of disease and of that of drugs. This revision made, the science of therapeutics will enter upon a new era; it might then reclaim the

epithet "rational" and repudiate forever the fumbling of the past.

2. Biological chemistry shows that there exists in diabetic patients an exaggeration of all the acts of general nutrition, and also an increase of activity in certain special organs, especially in the liver and the nervous system. The undeniable fact of overactivity of the general nutrition and of the hepatic cells influenced by a direct or reflex nervous irritation, should be the starting point for the therapeutics of diabetes. It may be affirmed in advance that every drug which slackens, in whatever manner it may be, the general changes and that of the nervous system, will diminish immediately the glycosuria. But a drug will only have a beneficial effect in diabetes if it retards the general excitation through the intermediation of its primitive action upon the nervous system, and if it does not exert too energetic a suspending influence upon the functions of this system. Therapeutic substances which accelerate demutrition should be done away with. It has been shown, clinically and experimentally, that they have produced no favorable results whatever.

3. The therapeutical indications in diabetes may consequently be formulated as follows: *a.* Withdraw from the organism, by a proper diet, the materials assisting in the formation of sugar, and free the hepatic cell from the agent irritating its functions. *b.* Slacken the general dis-assimilation and the formation of glycogen by the aid of therapeutic means which diminish the clinical actions of organic life through the intermediation of their primitive action upon the nervous system.—*Gazette Médicale de Paris*, Vol. vi, No. 26, 1889.

ON SCIATIC NEURITIS IN THOSE WITH VARICOSE VEINS.—Numerous observations attracted the attention of QUÉNU to the seemingly not rare coincidence of varices with a neuralgia appearing in the clinical form of a typical ischias. The symptoms in question are not the troubles complained of by most persons afflicted with varix, heaviness, sleeping of the lower extremities, cramps in the calves, etc., but neuralgic pains in the whole length of the nervous ischiadicus, which may be produced also by pressure upon the well-known points. Of 61 patients afflicted with varix, 6 consulted Quénu not on account of the latter, but for the neuralgia; in 31 out of 56 other cases in which the patients did not complain of spontaneous pains, pressure upon certain points of the sciatic produced them. The neuralgias were not very acute and did not manifest themselves in the form of attacks, but existed continuously in a moderate degree, and were felt especially after a walk or after standing for a long time. In the anatomical examination of the nerves Quénu repeatedly found varices in the veins of the sciatic, but he thinks that the pains were caused by a genuine neuritis, originating from a

phlebitis, not by the pressure of the varices upon the nerve-fibres. This neuritis gradually spreads from below upward, from the nervous tibialis post to the nervous popliteus, and to the sciatic. A disturbance of the peripheral nervous system caused by the obstruction of the circulation in the veins might give rise to trophic troubles in the skin, from simple erythema to varicose ulcers. Every patient suffering from ischias should, therefore, be examined for deep varices. If such are found a well-applied elastic bandage will often relieve pain more effectively than all other means.—*Centralblatt für Chirurgie*, No. 26, 1889.

**EXAMINATION OF THE BLOOD FOR THE EXISTENCE OF TYPHUS-BACILLI AS A DIAGNOSTIC MEANS.**—DR. JANOWSKI, of Kiew, did not succeed in proving the existence of typhus-bacilli in even a single one of the blood-samples taken from patients in whom abdominal typhus has been diagnosed with certainty. This fact, as also the results of the experiments of other investigators convince us that the probability of discovering typhus-bacilli in blood taken from the skin of a finger, of a roseola, or of a vein of a typhus patient, is but little. Janowski thinks it is so for this reason: "In the first place, the parenchymatous organs, especially the spleen, are the places where the typhus-bacilli accumulate; from here they are carried by the blood-stream into the general circulation only in small quantities, as is proven by post-mortem examinations of the blood of typhus patients; and we can take but little blood for diagnostic purposes. Perhaps more favorable results might be obtained if considerably more blood could be taken, in short, if a patient could be actually bled; but such a measure, even if not carried to the extreme, seems inexpedient in a disease as debilitating as typhus. For this reason the examination of the blood of typhus patients has no significance for diagnosis."—*Centralblatt für Bakteriologie und Parasitenkunde*, No. 20, 1889.

**ON PLEURISY CAUSED BY DIPLOCOCCUS PNEUMONIE.**—NETTER, reports in the *Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris*, 46 cases of pleurisy, 40 of which were caused by diplococcus pneumoniae; he distinguishes two kinds of pleurisy. The first kind occurs after pneumonia. It is generally of a purulent character and susceptible to cure, but frequently leads to perforation into the lung and pneumothorax. It often occurs epidemically during the months when pneumonia is most frequent. It occurs oftener in young people than in old people. As a mark of distinction from other pleurisy the author mentions that the exudate is creamy and does not easily separate into plasma and serum. Often the exudate accumulates in a circumscribed pleural sac and the disease takes a

chronic course. In 5 cases of this kind of pleurisy the author was enabled by the plate-cultures to prove the diplococcus pneumoniae.

The second kind of purulent pleurisy caused by diplococcus pneumoniae originates independently, *i. e.*, without pneumonia. The author called attention to the occurrence of this disease as early as 1886, and has observed 10 cases so far. He also mentions the observations made on this subject by Weichselbaum and Serafini. In 8 of his cases he instituted bacteriological researches and experiments on animals; four times he found the diplococcus pneumoniae alone, and four times he found it associated with the staphylococcus and streptococcus pyogenes. Supported by his observations, Netter believes that the greater number of purulent pleurisy occurring in children is caused by the diplococcus pneumoniae.—*Centralblatt für Bakteriologie und Parasitenkunde*, Vol. vi, No. 1, 1889.

**ON THE TREATMENT OF JUNCTA-ARTICULAR FRACTURES WITH MASSAGE.**—A. L. LAPERVENCHE says: The vicinity of a joint enhances the gravity of a fracture and demands appropriate treatment. As it must be our aim to aid the resorption of the blood discharged which, playing the rôle of a foreign body, is capable of causing a subacute plastic arthritis, massage appears certainly indicated. Facilitating the functions of secretion and excretion of the skin, rendering the afflux of blood easier, favoring nutrition and the contractility of the muscles, one of its most beneficial results will certainly be the avoidance of stiffness of the joint. Practice has begun to confirm this theory. Fractures of the lower limbs, of the radius, femur, humerus, elbow, knee-pan are treated with massage to the best advantage. In this way not only atrophy of the limb is avoided and the movement of the joint reestablished, but the cure is also more rapid.—*Gazette Médicale de Paris*, Vol. vi, No. 26, 1889.

**ON THE SEMIOTIC SIGNIFICANCE OF A RED LINE BORDERING THE GUMS IN TUBERCULOUS PHTHISIS.**—In an article on this subject published by G. STICKER in the *Münch. Med. Wochenschrift*, No. 37, 1888, the author declares that the symptoms which—as experience has shown—may precede phthisis (pseudo-chlorosis, different kinds of dyspepsia) are to be taken with great probability as a manifestation of latent phthisis if the red line bordering the gums exists simultaneously with them. In persons of youthful age it is undoubtedly so. The absence of this red line, under the circumstances, is without significance for the diagnosis in female patients; but where young male patients are concerned the probability of latent tuberculosis is very small if that red stripe on the gums is missing. The author illustrates the application of this theory by several observations.—*Centralblatt für Klinische Medizin*, No. 26, 1889.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, AUGUST 10, 1889.

THE NEW CÆSAREAN SECTION.

Two notable papers that relate to the "New Cæsarean Section" have appeared at a recent date. FRITSCH,<sup>1</sup> of Breslau, has modified the method of SÄNGER in two important particulars. In the first place, he has rejected the sero-serous suture. In a case of Cæsarean section, according to Säger's method, he loosened the elastic tube after the insertion of the muscle suture, to restore the circulation, when he was surprised to see the arrest of hæmorrhage before the introduction of the sero-serous suture. Observation of the conduct of the uterine walls after the enucleation of myomata and the insertion of the *étage* suture confirmed the impression that the Säger sero-serous stitch is superfluous. The way for this step, however, was prepared by Schroeder, who repeatedly asserted that the welting-in of the peritoneum was not only unnecessary, but also a source of danger, that best union could be effected by the juncture of the cut edges of the peritoneum. The second change in the technique of the operation is not less significant. Fritsch recommends that the uterine suture be used to include all the tissues—decidua, muscle and peritoneum—instead of the muscle and peritoneum only as practiced by Säger. If the case is operated on early, the cavum uteri is aseptic, and its sterilization by irrigation and iodoform is purposeless. The decidua is as sterile as the muscularis. Moreover, when the stitch is tightened, the thread rubs through the decidua and comes to lie upon the muscularis. The advantages of this simple suture are substan-

tial. Much time and trouble are saved—of moment in such an operation. Then, it is possible to effect a more exact apposition of the cut surfaces, and a firmer line of union by reason of the amount of tissue included. Hæmorrhage is also better arrested, when the entire thickness of the uterine parenchyma is embraced for some distance from the edge of the cut. Fritsch inserts the suture about 1 centimetre from the edge of the cut on the left side, passes it through all the tissues to a point distant about  $\frac{1}{2}$  centimetre from the internal edge; on the right side, the suture is passed from within outwards. The sutures are separated by a distance of 1 centimetre.

Against these modifications, but little on a *priori* grounds can be urged, seeing that Fritsch reports two successful cases. The chief danger in connection with the second item—the insertion of the suture through the decidua—consists in the liability to infection of the suture material, particularly if silk be employed. This danger is present even when the cavum uteri is aseptic at the time of operation; obviously, the risk is greatly increased, when the decidua is infected after attempts at delivery *per vaginam* and the like. On this subject, DR. BAYARD HOLMES<sup>2</sup> has well said: "It makes no difference how small an amount of infection gets into a solid spongy material like a piece of silk. Cells do not migrate into the silk suture far enough to drive out the infection and, as it were, granulate it off. Therefore, when the least end of a buried silk suture becomes infected, it is only a matter of time until colonization of the whole suture takes place. In the tissues surrounding the suture granulation tissue will appear, and a coagulation-necrosis of the wall of this sinus will cause a collection of pus to appear at the point of least resistance."

If further experience supports Fritsch's modification, the old classical Cæsarean section will be rehabilitated after its notable substitution first by Porro's supra-vaginal amputation and secondly by Säger's ingenious method. This fact, however, will not lessen the merit of the work of the observers just named. As remarked by Fritsch, "Säger's great services are universally recognized, they depend neither upon silver wire nor sero-serous suture."

The second paper, by H. THOMSEN,<sup>3</sup> contains

<sup>1</sup> Transactions of the Gynecological Society of Chicago, June 21, 1889.

<sup>2</sup> Centralb. f. Gyn., No. 24, 1889. (Original—Mittheilung.)

<sup>3</sup> Centralb. f. Gyn., No. 23, 1889. (Original—Mittheilung.)

the results of an experimental study of the best suture material that may be used in intraperitoneal operations, in general, and in Cæsarean section in particular. The experiments were performed on rabbits, cats, and bitches, immediately after they had cast their young. Incisions several centimetres in length were made through the right and left horns of the uterus, and these cuts were united with the suture materials under investigation. Different material was used to unite each cut. Sutures were also placed in the omentum and abdominal wall, to test not only the behavior of the ligature, but also the relative absorptive powers of the sites selected as compared with the uterus. The materials used were carbolic catgut, chromic acid catgut, silk and silkworm-gut. All materials were sterilized, as demonstrated by control cultures.

Thomsen draws the following conclusions: 1. Silk is the safest and best suture material, because it can be absolutely sterilized, and in time is absorbed. 2. Chromic acid catgut, silkworm-gut, like silver wire, are incapable of resorption, and ought not to be used. 3. Carbolic catgut, like all forms of catgut, ought to be rejected on account of the danger of infection. Moreover, carbolic catgut is unfitted for large intra-peritoneal wounds by reason of its rapid absorption.

The methods of this investigation are well chosen, and the conditions of the experiments eliminate common sources of error. Thomsen's conclusions, accordingly, may be accepted as decisive in the vexed question of suture material, for the time being at least.

#### PRURIGO SECANDI.

PROFESSOR LÉON LEFORT, editor, or more accurately speaking, author of successive issues of *Malgaigne's Surgery*, and one of the leading operators in France, is not a person whom even the most venturesome of recent graduates will be apt to accuse of undue timorousness in matters clinical. Much weight may, therefore, happily be attached to a warning from such a source against the reckless and ill-considered abuse of the knife, which has unfortunately been rendered possible by the introduction of anesthetics and antiseptic measures, and which has reached so far that the legitimate field of surgery has often been abandoned in an apparent endeavor to ascertain how

much vivisection is compatible with the temporary maintenance of life.

Among the things which have almost become affairs of everyday routine, LeFort remarks, cancerous stomachs have been resected, the spleen and the kidney extirpated, vesical tumors removed, the uterus and tubes ablated; multitudes of women have been castrated, even when the ovaries were healthy: the knee-joint has been opened to suture a simple fracture of the patella; the abdomen opened to fasten to its wall a prolapsed uterus, or even solely for diagnostic purposes, etc.; and he cites an instance wherein a surgeon, to spare a young woman's modesty the inconvenience of a vaginal examination, preferred an exploratory laparotomy, with the satisfactory result of discovering that there was no abdominal lesion. Certain operators of established notoriety, or even their junior imitators, find occasion to perform their favorite procedure hundreds of times within a few months; be it thyroidectomy, nephrectomy, hysterectomy, salpingotomy, radical cure of hernia, or aught else. Of this, the author says: "When I see the multiplication of successive operations for affections which a hospital experience of more than forty years has shown me to be either relatively rare or curable by non-operative treatment, I am led to believe that many of these surgeons, instead of asking themselves what operation the disease and the hopelessness of any other treatment compels them to perform upon the patient, inquire rather who is the patient whom they can induce to undergo the operation just then under consideration not to say in fashion."

Several influences combine to encourage this operative craze, and of these the first to be mentioned is the pecuniary appetite which threatens to degrade the healing art to the level of a trade. Verneuil is quoted as intimating that some surgeons who persuade a patient to risk the speedier possibilities of the knife, with argument that "time is money," may be suspected of a mental reservation which whispers "operation is money also," and it is even alleged that in Paris—let us hope nowhere else—a commission on the operator's fee is given to the physician who procures the case, so that the latter is tempted rather to seek the specialist who will insist on the most lucrative, if unnecessary, operation, than to consult the surgeon who can give the wisest ad-

vice. The public, hearing of brilliant successes, but ignorant of possible dangers and disastrous failures, and impatient of the tediousness of safer and surer medical treatment, is readily induced to fly to evils that it knows not of, and thus aids skilled hardihood in bringing needlessly heroic measures more and more into vogue.

A fanatical and exaggerated confidence in anti-septic methods plays no small part in perpetuating the abuse. If ovariectomy be fatal in one seventh of the operations performed, hysterectomy in one fourth, nephrectomy in one-third, or laparotomy for myomata in one-half, the deaths are attributed to neglect of some minor detail—to the employment of an ill-prepared ligature or the omission of this or that petty precaution against the entrance of a few stray "germs,"—and the blame is ascribed to the individual surgeon, not to the operation.

The principles which should guide the true surgeon's intervention are these: The fact that an operation is capable of curing a disease is not in itself a justification for operating; the gravity of the operation must be compared with the gravity of the disease; the benefit to the patient must be proportional to the danger to which he is exposed. It is not admitted that the mortal character of a malady is a sufficient reason for desperate expedients. There are cases where the surgeon must recognize the impotence of his art; his first consideration should be to avoid doing harm, and he should learn to abstain whenever the immediate dangers of active interference are greater than the temporary amelioration that may be hoped for. He should not imperil life to relieve an infirmity or deformity which does not menace existence, unless it be such as to incapacitate the sufferer from earning a livelihood. Ankylosis in a position rendering a limb useless, extreme genu valgum, exaggerated rhachitic distortions, ulcerated talipes preventing walking, may warrant resection, osteotomy, or even amputation, but it is a different thing to expose a patient with reducible hernia to the risk of immediate death in order to save him the annoyance of wearing a truss, or to avert the improbable chance of a strangulation twenty or thirty years later. The interest of the patient is to be placed above all other considerations; a cure sought by the surest and least hazardous therapeutic means rather than by dangerous displays of dexterity;

solicitude for the sanctity of human life, should override professional ambition or monetary covetousness. If any case give cause for doubt, let the surgeon pause and ask himself "what he would do, what he would advise, if the question concerned his mother, his wife, his child; and let the answer dictate his conduct. So will he often reject perilous heroic exploits; he will perform fewer operations; he will acquire notoriety less easily, and fortune, perhaps, not at all; but he will be sure of fulfilling his duty as a good and honest surgeon, and of being regarded by his patients as *vir bonus medendi peritus*."

The warning which we have briefly transcribed from its foreign source is reproduced in all its fervid eloquence by the *Gazette Médicale de Montréal* from the latest edition of the *Médecine Opératoire*, of Malgaigne and LeFort, and most of our readers will be willing to admit its pertinence—at all events, to France. In displaying the beam which obscures the surgical eye of continental Europe, it would, of course, be invidious to suggest the possibility that ophthalmic introspection might detect a mote in our own.

#### EDITORIAL NOTES.

##### HOME.

DR. THOMAS WATERMAN, of Boston, is said to be the most skilful ventriloquist in that city.

DR. WILLIAM WARREN POTTER, of Buffalo, N. Y., has had conferred upon him the degree of Doctor of Medicine, *Honoris Causâ*, by the Kentucky School of Medicine.

THE AMERICAN SOCIETY OF MICROSCOPISTS commences its annual meeting at Buffalo on the 20th inst.

EPHRAIM CUTTER, M.D., LL.D., F.S.Sc., has received a gold medal from the Society of Science, Letters and Art of London, for his paper on "The Relations of Medicine and Music," and also for one on "Hygienic Drinks" and one on "Cleaned Whole Wheat."

DR. WILLIAM HAILES, JR., of Albany, N. Y., will read a paper on "Intubation of the Larynx" before the meeting of the British Medical Association.

AN EPIDEMIC OF DYSENTERY.—Dysentery has become epidemic at Warsaw, Ill., and the people

are becoming greatly alarmed. Fifteen deaths have occurred since the 29th ult. Four died on the 1st inst. and four on the 2d. It is now estimated that at least 180 cases exist in Carthage, Ill., and it is feared many of them cannot recover. The victims are taken suddenly and die in a short time. The disease has appeared at Hamilton, and is said to be epidemic at Canton and Cahoka, Mo.

ASSOCIATION ITEMS.—Drs. D. Webster Prentiss, of Washington, and L. Duncan Bulkley, of New York, are the delegates to the meeting of the Canadian Medical Association. The name of Dr. Kinyoun should have appeared in the Annual Report of the Committee on State Medicine in place of Dr. S. T. Armstrong. Dr. Charles W. Brown, New York, is a member of the Committee on Necrology, not "J. W. Brown."

THE CANADIAN MEDICAL ASSOCIATION.—We again call attention to the fact that the annual meeting of the Canadian Medical Association will be held at Banff, a station on the Canadian Pacific Railway, in the heart of the Rocky Mountains, at the entrance of the "Canadian National Park." The meetings will be held on August 12, 13 and 14. The British Medical Association and many societies of the United States have been invited to attend. Special rates are offered by the railway company. Application should be made to the General Secretary of the Association, Dr. Bell, whose address is Union Avenue, Montreal.

SANITARY PROGRESS.—Why is it that our State Legislatures do not take more interest in enacting laws to secure immunity from preventable diseases arising from inadequate sanitary regulations or the enforcement of existing laws? *The Sanitary News* in commenting on this subject says: "Legislation seems to be the greatest obstacle in the way of sanitary progress. Science has made plain the duties of officers and citizens, but legislation is tardy in providing means for their enforcement."

#### FOREIGN.

FATHER CONRADY has been stricken with leprosy at the leper settlement in Molokai.

A UNIVERSITY under British tuition is being established at Peking, China, and the College of Medicine in affiliation therewith is in working order.

FEMALE MEDICAL PRACTITIONERS in Russia are forbidden to attend adults of the male sex.

IN GERMANY the Government has come to the conclusion that there are enough medical colleges in the country and refuses to allow any more to be organized. PROF. FRESSENIUS, of Wiesbaden, after a long series of chemical analyses, declares that an egg contains as much nourishment as a pound and an ounce of cherries, a pound and a quarter of grapes, a pound and a half of russet apples, two pounds of gooseberries, and four pounds of pears, and that 114 pounds of grapes, 127 pounds of russet apples, 192 pounds of pears, and 327 pounds of plums are equal in nourishment to 100 pounds of potatoes.

IN FRANCE the Director of the Assistance Publique has distributed among the *infirmiers* and *infirmières* of the Paris hospitals 2,000 tickets for the Paris Exhibition. The decoration of the Legion of Honor has been conferred upon Dr. Allan Herbert, physician to the British Embassy at Paris. The French Society for the Advancement of Science is now in session. The practical sanitation of the Paris Exhibition is said to be execrable. The Minister of the Interior has given 1000 francs to the Paris Ambulance Organization.

IN GREAT BRITAIN the Privy Council has issued an order in the City and Metropolitan District of London that dogs are to be muzzled, except those actually employed as sporting dogs or in the capture of vermin. The spread of rabies has brought forth the order. Unmuzzled dogs will be slaughtered, as also will those with or suspected of rabies, or having been bitten by a rabid dog. The Princess of Wales has accepted the Presidency of the National Pension Fund for Nurses. The weekly issue of the *British Medical Journal* has reached 15,550 copies. Professor Struther has resigned the Chair of Anatomy at Aberdeen University. An exhibition of electrical appliances is now open at Birmingham and will continue for three months. Deputy Surgeon-General Francis Day, a distinguished officer and naturalist, died at Cheltenham on the 10th ult. The sanitary condition of Glasgow is very bad, and the Corporation is considering the necessity of applying to Parliament for increased sanitary powers. The London Hospital has become affiliated with the National Pension Fund for Nurses.

## TOPICS OF THE WEEK.

## PHYSIOLOGICAL LIMITATIONS.

From the able address of DR. DAVID W. CHEEVER at the annual meeting of the American Surgical Association held in Washington, May 14-16, 1889, we make the following brief extract:

"When we consider physiology we are struck both by its great progress and by its imperfections. The older physiology is obsolete and discarded, but in the newer physiology the functions of some large and important organs are still undetermined. The ductless glands, for instance, the spleen, the thyroid, the thymus and the supra-renal capsule.

"An ignorance of their function renders the surgeon unable to predict the consequences of their removal. Of what avail the brilliant operation to excise a double goitre if it is to be followed by an obscure degeneration of the nervous or glandular system? Again, in organs of known function the limit of the digestive power of different portions of the alimentary canal is not yet definitely learned.

"How can we get along without a gall-bladder? How important is the pancreas? Can the duodenum supplant the stomach in nutrition? How much ileum can be removed without starvation? What will the rectum digest? All these are pertinent questions for the physiologist, and have a direct bearing on modern surgery."

## PRESIDENTIAL ADDRESSES.

At the last annual meeting of the Ohio State Medical Society the President, DR. P. S. CONNER, dealt with the conventional "President's Address" after this fashion:

"As is the appendix to the intestinal tract, a useless survival of a once important organ, so is the presidential address to the annual proceedings of the State Medical Society. In the days when books and journals were few, communication slow, professional work physically harder than at present, there was, I doubt not, good reason for requiring of the recipient of high honors an abstract of the year's progress, suggestions of the work that might and should be done, or reports of diseases and injuries carefully investigated and successfully treated.

"Now that to each one of us what appeared in print but a short time ago in San Francisco, Boston, Vienna or St. Petersburg is familiar talk, it may be well asked of the inaugural address, *Cui bono?* Hardly yours; surely not his to whom the months of prospect of its preparation are as the fly in the ointment of the apothecary. But custom is imperious and we are all its slaves. Like my predecessors, I obey its mandates."

## CAFFEINE AS A TONIC.

DR. HENRI HUCHARD has some good observations to present on the use of caffeine as a tonic or excitant in adynamic states. He considers it much superior to ether, which may be more exciting but is much less tonic in its action. The diuretic action of caffeine is now admitted by everybody, but its cardiac action is still contested. One point in the use of caffeine in adynamic states is

that it can be given in considerable quantities without danger. In one case of extreme weakness (with from forty to fifty stools a day) as many as ninety-five hypodermatic injections of caffeine were given in a month. Dr. Huchard uses these injections with great freedom in typhoid fever at the Bichat Hospital, as well as in cases of serous pneumonia, and reports a number of cures in very grave cases. In experiments that M. Huchard made on animals, he found that the drug acted on the nervous system, and Semmola, (of Naples) states that its principal action is on the medulla oblongata. In any case two important facts are evolved from Huchards' experiments: First, that caffeine has a remarkable efficacy in large hypodermatic injections in all adynamic cases. Secondly, it can be given in large doses without danger. M. Huchard employs the following formulas: R. Caffeine, 2 grams; benzoate of sodium, 3 grams; and distilled water, 6 grams. The solution must be made while hot. Each syringe-ful contains 20 centigrams of caffeine. Sig.: Inject 6 to 10 syringe-fuls *per diem*. The second formula is: Caffeine, 4 grams; salicylate of sodium, 3 grams; distilled water, 5 grams. Here the syringe contains 40 centigrams of caffeine, and from four to five injections are given each day.—*Paris Correspondence New York Medical Journal*.

## LEPROSY IN MADRAS.

According to census returns, the proportion of lepers amongst the population of Madras 4.4 per 10,000 against 5.2 in Bengal and 8.5 in Bombay; but there is reason to believe that these figures fall short of the actual extent of the disease. In Madras it is on the whole slightly more prevalent in coast districts than in inland, the ratios being 4.9 in the former, and 4.4 in the latter per 10,000 of population. The proportion of lepers in the several districts ranges from 2.0 in Coimbatore to 10.5 in Madras City. The districts showing the highest ratios next to Madras are Nilgiris 8.0, Tanjore 7.0, and Chingleput, Malabar, and North Arcot each 6.0 per 10,000. The disease attacks Europeans and Eurasians as well as natives, but is most common in natives. The propagation of leprosy is no doubt largely influenced by heredity, but recent observations appear to show that it is also contagious. In localities in which lepers are at large with the disease in an active state, and having open sores, there seems to be an increased tendency to fresh cases amongst the general population. As regards the part which heredity plays in the transmission of leprosy, we know that persons with the disease in an active state have diminished fecundity, and that mortality runs high amongst the offspring of lepers. These two peculiarities, therefore, tend to keep in check the leprous population, but I have no doubt that it is increased by contagion and probably other influences. That segregation is of value in holding the disease in check seems well established, but to be of much value in India it would require to be carried out on a more extended scale than at present.—*Surgeon-General Bidie, British Medical Journal*.

## CHLOROFORM IN OBSTETRICS.

In regard to the use of chloroform in obstetrics, M. BUDIN gives numerous cases to prove that labor pain can

be lessened by quite small doses of chloroform in most cases. It is given here in the manner called "*Queen's chloroforming*," that is to say, just enough to dull sensibility. In a few cases, however, it is necessary to proceed to complete anaesthesia, which does not prevent labor going on to a successful issue. The principal indication for the use of chloroform in labor is found in extreme pain. Often it is only during the period of expulsion that it is needed, but when the pains are intense during dilatation it may also be used. Rigidity of the os uteri is an important indication. There is an extraordinary degree of tolerance in parturient women for chloroform, so that the contra-indications are extremely few.—*New York Medical Journal*, July 27.

#### NATURAL ELECTRICITY.

An extraordinary tale comes from Burmah. Mr. Ronald H. King, an electrician well-known to the Burmese, while on a prospecting and shooting expedition in the island of Labuan, is said to have discovered a mineral from which electricity can be obtained without apparatus of any kind whatever. The mineral is described as being in the form of a black stone, of excessive hardness, and very great specific gravity, being nearly as heavy as platinum. A small block in the shape of an irregular cube, measuring 4.3 inches one way, by 5.2 inches the other way was brought away, and on bringing it into the testing room, a strong effect was noticed upon the galvanometer. At first it was thought that the mineral was an ordinary loadstone, but on tests being made, it was found that the force was more akin to that of an electro-magnet, and that a strong current would flow when the mineral was connected in a circuit. Further tests revealed that a difference of potential of forty-seven volts could be detected at the extremities, the internal resistance of the mass being twenty ohms. The block appears to waste away very slightly, leaving a slight gray powder upon the surface when connected up for some time. The electrician now uses the block to light a couple of incandescent lamps in his laboratory!—*Times and Register*.

#### SPECIAL HOSPITALS.

*The Boston Medical and Surgical Journal* of July 25th devotes a page to a review of an address recently delivered in London by SIR ANDREW CLARK, President of the College of Physicians. After an eloquent plea for the generous support of the larger hospitals, he pays his respects to a class of special hospitals who seek to divert and divide the public charities, after this wise:

"A doctor who cannot get on in the ordinary way takes to studying the great toe, and he discovers something about it never before known. In the course of his studies he ascertains that the diseases of the organ are not only supremely important in themselves, but that they have the most intimate relation to all the other serious diseases of the body. He also invents a wonderful instrument, whereby he can look into the great toe and see what is threatening, and prevent all those terrible things which happen in the organ and affect the whole system. He goes to his friends, shows them his instrument and tells them of his discoveries. They then club together and establish a Hospital for the Treatment of Diseases of the Great Toe.

They soon get patients who are convinced of the vast importance of the diseases of the great toe. Marvelous cures are effected, and all sorts of frightful diseases are prevented. They have an annual meeting. They have a Chairman who sets forth bashfully in the presence of the great physician the diseases of the great toe, the wonderful things that have been done, the service which has been rendered by the hospital, the terrible prejudice it has had to encounter, and the determination that this great institution shall be liberally supported, notwithstanding the prejudices of the medical profession and of those who herd with them."

In all seriousness he raises the question whether special hospitals have not been overdone in London, and the contributions of benevolent people directed to unwise uses. And the journal from which we quote raises the question whether there is not a growing tendency in this direction in our own large cities.

#### POISONING WITH ACETANILIDE.

Before the Baltimore Medical Association, DR. J. E. GIBBONS recently read a paper on the results of a mistaken dispensing and administration of a one-drachm dose of acetanilide where five grains of antipyrin had been intended. The *Maryland Medical Journal* for July 6th contains a brief account of the symptoms, which were those of cardiac depression, cyanosis, and nausea. The treatment, which removed the threatening prostration, consisted of the use of tincture of belladonna and brandy. The headache, for which the dose was taken, was not relieved, and Dr. Gibbons holds that if the second dose had been repeated in two hours, as the mistaken directions ordered, death would have been the result. There was an error on the part of an apothecary, it is alleged, in writing out the copy of a prescription, causing the substitution of three drams of acetanilide for half a drachm of antipyrin. It was a case of unauthorized "borrowing" of a prescription by a neuralgic person who had not been prescribed for by a physician. The antidotal doses of belladonna consisted of four drops of the tincture, every half-hour, for four hours, and at wider intervals afterwards.—*N. Y. Medical Journal*, Aug. 3, 1889.

#### WILKESBARRE'S BAD WATER.

A despatch from Wilkesbarre, Pa., states that the typhoid fever epidemic in that city does not appear to be on the decrease. The total number of deaths within three weeks is thirteen. According to a well established rule in typhoid, that the death-rate runs at from 10 to 12 per cent., this makes a certain existence of over 100 cases in the city. It is highly probable that the total number of cases is largely in excess of that number. Dr. L. H. Taylor, representing the State Board of Health, made an examination of the water-supply system of the Wilkesbarre Water Company, and his report confirms the first theory of the cause of the disease. He finds there are twenty-five or thirty houses along the course of Laurel Run, the stream from which the water is taken, and holds the belief that the excessive rains of last month washed the refuse of these houses into the stream. In addition to the typhoid fever cases there are a great number of cases of malarial fever, dysentery, and kindred diseases.

## SOCIETY PROCEEDINGS.

### AMERICAN MEDICAL ASSOCIATION.

#### Fortieth Annual Meeting. Report of Sections.

##### *Sections on Diseases of Children.*

##### FIRST DAY, JUNE 25.

The Section was called to order by the Chairman, DR. JOHN A. LARRABEE, who delivered an able and eloquent address. He congratulated the Section on the opportune time and pleasant place of the meeting, and said that none could be more fitting for the burial of professional animosities. An earnest plea was made for the rejection of the amendment to the constitution pending before the Association to abolish the Section on Diseases of Children, and spoke highly of the good work that the Section has and can accomplish.

On motion of DR. CHRISTOPHER, of Ohio, the Section unanimously resolved to continue as a distinct Section, and a committee of three were appointed to bear the resolution to the general Association, and defend the continued autonomy of the Section.

On motion of DR. E. F. BRUSH, of New York, the recommendations of the Chairman's address were referred to a committee, composed of Dr. Brush, of New York, Dr. Christopher, of Ohio, and Dr. Watson, of New Jersey.

DR. T. B. GREENLEY, of Kentucky, read a paper on *The Management of Infants during the First Year*. The doctor gave statistics of the alarming mortality during the early years of infant life, and carefully reviewed the causes for it. He recommended the better education of mothers, and advocated greater care of the infant in every particular. Syphilis, in his experience, was a frequent disease.

The paper was discussed by Drs. Senta, of Texas, Whitney, of Rhode Island, Watson, of New Jersey, and Latimer, of Maryland.

DR. E. F. BRUSH, of New York, read a very valuable paper on *Cow's Milk for Infant Food*. The doctor took the position that cow's milk was the best and only practical substitute for the mothers, and showed that if as great energy were bestowed upon improving the quality of it, by overseeing its source and its can after milking, as has been given to the manufacture of various chemical foods, great improvement in infant feeding would result.

DR. J. A. JEFFRIES, of Massachusetts, commended Dr. Brush's paper, and advocated sterilizing, when the milk cannot be obtained perfectly fresh.

DR. CHRISTOPHER, of Ohio, commended the points made by the doctor on the management of dairies. In Cincinnati he had seen some deplorable instances in the manner of caring for milch cows.

The paper was further commended and discussed by Drs. Sheldon, of New York, Latimer, of Maryland, Gates, of Pa.

On motion of DR. WATSON the Secretary was instructed to preserve the records of the Section, and to give them to his successor.

On motion of DR. W. P. WATSON a committee of three were appointed, to bring in nominations for Chairman and Secretary of the Section for the ensuing year.

##### SECOND DAY, JUNE 26.

The Section was called to order at 2:15 P.M. Dr. J. A. Larrabee, Chairman.

A paper by DR. N. GUHMAN, St. Louis, Mo., on *Summer Diarrhoea and Dysentery* was read by title.

DR. PETER HOOPER, of Philadelphia, Pa., read a valuable paper on *The Intestinal Diseases of Children during Hot Weather*.

The paper was discussed by Drs. W. P. Watson, Jersey City, I. N. Love, St. Louis, Mo., and the Chairman.

The paper, *Heart Failure in Diphtheria*, by DR. G. W. JONES, was read by title.

The paper on *Intubation of the Larynx with report of Cases* was read by DR. F. E. WAXHAM, of Chicago. The doctor reported continued success in the operation.

The paper was ably discussed by Drs. G. W. Gay, of Boston, and Whitney, of Rhode Island.

DR. H. D. CHAPIN, of New York, read a paper on *Pseudo-Membraneous Rhinitis*. The doctor held that there was a pseudo-membraneous rhinitis which was distinct from diphtheria, and that it was a comparatively mild affection.

DR. COHEN, of Philadelphia, agreed with the doctor in there being each a disease distinct from diphtheria.

DR. WHITNEY thought the gentleman had described cases of nasal diphtheria.

DR. C. R. EARLY, of Ridgeway, Pa., read an exhaustive paper on *Scarlatina*.

The committee on nominations reported the name of Dr. I. N. Love, of Missouri, for President, and Dr. E. F. Brush, of New York, for Secretary of the Section for the coming year.

The Report was unanimously adopted.

##### THIRD DAY, JUNE 27.

Section called to order by the Chairman.

The committee on the Chairman's address reported that they had met with the Committee on Dietetics of the Association, and had adopted the following preamble and resolutions:

WHEREAS, Certain garbled extracts from the proceedings of this Committee on Dietetics, and the Section on

Diseases of Children, have been published in medical journals as advertisements, and thereby have reflected upon this Association; therefore be it

*Resolved*, That the Committee on Dietetics and the Section of Diseases of Children, have not in the past, or do they now, commend any of the proprietary preparations used as foods, and

*Resolved*, That the said Committee and Section earnestly protest against the action of manufacturers in charging partiality for any food, and they hereby, condemn the action of those medical journals which have published such advertisements, and further,

*Resolved*, That a copy of these resolutions be sent to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for publication.

E. A. Wood, M.D., Chairman Committee on Dietetics; Frank Woodbury, M.D., Secretary. J. A. Larrabee, M.D., Chairman Section on Diseases of Children; C. G. Jennings, M.D., Secretary.

A paper by DR. M. P. HATFIELD, of Chicago, on *The Value of Hydrogen Dioxide in the Treatment of Children*, was read by title.

A paper by DR. D. S. BOOTH, of Sparta, Ill., on *Penal Rule in Public Schools*, was read by title.

DR. S. P. DEAHOFE, of Potsdam, O., read a paper on *Polio-myelitis Anterior Acute*, in which he related cases showing the difficulty in diagnosis often experienced, and the inutility of most forms of treatment. He had seen no benefit from electricity.

Discussed by Drs. King, of Chicago, and Peter Hooper, of Philadelphia.

DR. I. N. LOVE, of St. Louis, read a valuable paper on *One Year of Acetanilide in Pediatric Practice*, in which he commended the remedy very highly in various febrile diseases, chorea and whooping cough, and praised the drug above antifebrin as an antipyretic and analgesic.

The paper was further discussed by Drs. Dixon, of Kentucky, Hill of New Hampshire, King, Watson, New Jersey, Atkinson, Larrabee, and Osler.

DR. J. C. WILSON's paper on *Visceral Neuralgias in Children* was read by title.

DR. WM. PERRY WATSON, of Jersey City, read a paper on *Atropin in Enuresis*. Had found usually good results from the use of the drug. He had given the remedy in thirty cases, 1 gr. to 1 oz., one drop each year.

The papers were discussed by Drs. Love, Larrabee, Knapp, of Boston, and Jeffries, of Boston.

#### *Section of Dental and Oral Surgery.*

FIRST DAY, TUESDAY, JUNE 25.

The Section was called to order by DR. F. S. TALBOT, Secretary of the Section, who announced the fact of the death of Dr. F. H. Rehwinkel, of Chillicothe, O., Chairman of the Section, which occurred on June 8, 1889.

On motion of DR. JACOB L. WILLIAMS, of Boston, Dr. W. W. Allport was elected Chairman *pro tempore*.

DR. J. S. MARSHALL, of Chicago, moved the

appointment of a committee of three to draft suitable resolutions upon the death of Dr. Rehwinkel. The following committee was chosen: Dr. W. W. Allport, of Chicago, Chairman; Jacob L. Williams, of Boston; and W. X. Sudduth, of Philadelphia.

DR. W. H. ATKINSON, of New York, read a paper on *The Origin of Pus*. A *résumé* of the paper is as follows:

1. Inflammation is a disturbance of nutrition of a tissue causing a recurrence of the embryonal condition of the tissue involved.

2. The embryonal condition is established by the breaking up of the tissue into those medullary or indifferent corpuscles which at an early stage of normal development have built up the tissue.

3. The medullary corpuscles arise not only from the protoplasmic bodies of the tissue, the so-called "cells," but also the intercellular or basis substance is productive of such corpuscles, as these have shared in the formation of basis substance in the process of normal development.

4. The medullary or indifferent corpuscles will still represent a tissue so long as they remain interconnected and continuous. By a simple reappearance of basis substance the most favorable termination is established, so-called "resolution."

5. If the inflammatory or medullary corpuscles have largely augmented, a number thereby remaining in original connection, the result will be productive, viz.: with a newly formed tissue of unusual size, a so-called "hyperplasia."

6. If the inflammatory corpuscles spring from previous "cells," basis substance and blood-vessels break asunder and become isolated, they will be suspended in an albuminous liquid, they will henceforth represent pus corpuscles.

Pus, therefore, is a destroyed tissue broken up into its constituent elements, and as such unfit for production of a new tissue, although the single pus corpuscle will remain alive and amoeboid almost indefinitely, as long as they are sufficiently nourished.

8. The emigration of colorless blood corpuscles certainly participates in the formation of pus and in the purulent discharge of proud flesh or granulation tissue, and is probably the main source of the pus.

9. Suppuration is caused by the presence of certain microbes, mainly the three varieties of staphylococcus, only when a previous inflammation be present in the tissue, furnishing a favorable soil for the development of the before mentioned microbes.

10. Staphylococcus is not the only antecedent of suppuration, it having been proved by experiments that the introduction of certain chemical agents unfavorable to the development of microbes may likewise be followed by suppuration.

The paper was discussed by Drs. Sudduth, Williams and Brackett.

DR. WM. CARR, of New York, then read a paper on *Diseases of the Antrum*, in which he refuted the statements frequently made by rhinologists that a large majority of the cases of antral diseases are caused by chronic rhinitis, polypi and other nasal diseases. The author claimed that 80 per cent. of all cases of abscess of the antrum were the result of diseases of the teeth, usually that of pericemental alveolar abscess, alveolo-pericementitis and necrosis. He has operated during the last eighteen months upon fourteen cases referred to him by a nose and throat specialist, of which none were caused by chronic rhinitis, none from hypertrophic rhinitis, one from dentigerous cyst, two from polypi, and eleven from diseased teeth.

The paper was discussed by Drs. Marshall, Sudduth, Atkinson, Williams, Talbot, and Brackett.

DR. W. W. ALLPORT, of Chicago, read a paper upon *Facial Neuralgia Associated with Pregnancy*. The author was not satisfied with any definition of the term "neuralgia" that he could find or any that he could make himself. He believed that neuralgia of the face, and especially of the teeth, was largely due, not to reflex neuroses but rather to the hyperæmic condition of the upper half of the body so constantly present during pregnancy. This hyperæmic condition is a prolific source of irritation to the nerve filaments of the mucous membrane, the skin of the face and the pulps of the teeth, and through this irritation most of the cases of neuralgia of the fifth pair of nerves had their origin.

The paper was discussed by Drs. Williams, Brackett and Atkinson.

On motion a committee on nomination of officers for the Section was appointed by the Chairman, consisting of Drs. Talbot and Marshall.

The Section adjourned to meet at 2 o'clock on Wednesday afternoon.

#### SECOND DAY, JUNE 26.

Section called to order by Dr. W. W. Allport.

The Committee on Nominations reported: For Chairman of the Section, Dr. Jacob L. Williams, of Boston; for Secretary, Dr. E. S. Talbot, of Chicago.

DR. J. S. MARSHALL, of Chicago, read a paper entitled, *The Oral Cavity of Pregnant Women*. The author described the changes which take place in certain cases of pregnancy in the blood, bones, teeth, excretions and secretions. Special attention was given to the conditions of the secretions of the mouth and the diseased conditions of the mucous membrane, gums and the teeth. The author claimed that in certain cases of pregnancy nutrition was impaired and as a result the bones and the dentine became abnormally soft, and that this softening of the dentine predisposed the teeth to decay. Overwork and mental strain also rendered the teeth predisposed to caries. The acid

condition of the salivary secretions augmented the action of the bacterium lactis in the production of caries.

The acids found in the mouth during pregnancy are the acetic, hydrochloric, uric and oxalic.

Lactic acid was the exciting cause of caries, as proved by Miller, of Berlin, but that he believed that the acids just named greatly augmented its action. Gingivitis and phagedenic pericementitis were often associated with pregnancy. The author called attention to the fact that in patients affected with phagedenic pericementitis there was often associated with it rheumatic affections, diabetes mellitus or albuminuria, and that during pregnancy these diseases of the mouth ran a more rapid course than in other cases. The exalted nervous state of the patient precluded severe or extended operations upon the teeth as miscarriage might be the result. Temporary fillings only should be inserted at such times.

This paper was discussed by Drs. Williams, Sudduth, and Andrews.

DR. E. S. TALBOT read a paper on *Statistics of Constitution and Developmental Irregularities of the Jaws and Teeth of Normal, Idiotic, Deaf and Dumb, Blind and Insane Persons*. He gave some of the theories which are generally held up to the present day. He then gave tables of irregularities of the teeth of healthy persons, one made by Dr. Ottofy, of Chicago, in which 317 males and 306 females were examined, showing that the largest percentages of irregularities was observed at the age of 8 years. The cuspid teeth appearing at this period was the cause, and that nature corrected most of these irregularities later in life. The author has examined the mouths of 1000 patients, showing 78 per cent. of normal cases and 22 per cent. of irregularities of the teeth. In 1,977 idiots 55.3 per cent. were normal, while 44.97 per cent. were abnormal. In 1,935 cases of deaf and dumb cases showed 45.5 per cent. normal and 54.95 per cent. irregularities.

In the examination of the mouths of the blind it was difficult to examine their mouths because of their sensitive nature. There were however enough examinations made to give a fair idea of the condition of the teeth and jaws. Out of 207 cases 50.7 cases were normal, while 49.97 cases irregularity. In 700 cases of insane cases 620 were normal and only 80 cases of irregularity. It will therefore be observed that in neurotic patients in which the disease is present at birth about one-half are afflicted with irregularities of the teeth, while in normal individuals, and also in insane cases, in which the disease is manifested after maturity, only about 20 or 25 per cent. of cases are noticed.

#### THIRD DAY, JUNE 27.

The Section was called to order at 9:30 A.M. by the Chairman, *pro tem.*, DR. W. W. Allport.

The reading of the minutes of the previous meeting was dispensed with, and the Chairman introduced DR. W. X. SUDBUTH, of Philadelphia, who delivered a very interesting lecture upon *The Products of the Epiblast*, giving special attention to the rete malpighii as the formative layer in the development of glands, hair, teeth, nails, etc., also its relation to certain pathological conditions, such as epithelioma, carcinoma, and of the skin diseases. He laid particular stress upon the fact that the initiative step in the development of all the glands and tissues directly related with the skin was to be found in the deepest layer of the rete malpighii; which, as he plainly showed, was composed of oval and round cells, the bioplasts of Beale, and not of columnar cells as is generally understood.

The development of glands, sebaceous and sudorific, hair, and wool, the enamel organs of the teeth, etc., is the result of the evolution of a solid epithelial ingrowth which probably begins in the division of a single cell of the infant layer of the epiblast, which results in the formation of one of the above-named tissues, according to the hereditary tendency of the cell itself. The essayist dwelt on the fact that histologically it was impossible to differentiate between the several cells, as to whether they would form a hair, a gland, or the enamel organ of a tooth. They all have the same morphological appearance and give the same chemical reaction—and are also divided from the same layer of the epiblast. He held that each and every cell was a separate and individual unit, holding within itself an heredity tendency which governed the form of the resulting product. This was beautifully shown by the series of photo-micrographs, ranging from 200 to 1,250 diameters, in which the cellular structures were clearly defined—the development of a hair was followed from its incipency to the completion of a fully formed product, also the development of a tooth. The analogous development of the two up to the time when calcification begins in the latter, was graphically portrayed. It was also shown how that a new hair was derived from an epithelial bud which was thrown off from the deepest portion of the previous hair-bulb, and also that the cord for the formation of the permanent tooth arose in a similar manner from the side of the enamel organ of the temporary tooth. The speaker also showed the special connection of the deepest layer of the epiblast in the development of epithelioma and carcinoma. He said that the whorls of epithelial cells found in the former were not necessarily pathognomonic of epithelioma, in that similar nests of epithelial cells were to be found in embryonic tissues where rapid development was in progress, and that they were indications of the latter condition only. He showed a number of nests taken from sections of embryonic tissues, which were identical in their appearance

to the pearl nests found in epithelioma. In diseases of the skin he held that the deepest layer of the rete malpighii formed a very interesting field for investigation. The lecture was amply illustrated, and replete with information.

DR. ANDREWS' paper on *Pits and Fissures of the Enamel*, considered the etiology of decay at these points. He showed that pits in the enamel led to undermining decay of this tissue, and stated that these defects were more frequent than is generally supposed. These cavities, enlarging, reach the dentine, when infection and decay follows. He stated that the deep fissures in the grinding surfaces of the teeth often extended to the dentine, and that the dentine was generally defective within, the defect consisting of an interglobular formation at this point. This interglobular structure is more rapidly acted upon by the infection than is the normal tissue everywhere about it. This condition he considered largely hereditary. Exposure of the dentine is frequently caused by cracks in proximal surfaces near the neck, these being a source of infection equally with the pits and fissures of the grinding surfaces. Early infection was shown to fill the exposed tubuli with gas bubbles and granules. The gas bubbles are caused, probably, by the action of an acid on the lime cells of the dentine. This acid is given off as a waste product of the organisms. The bubbles may easily be mistaken for the organisms themselves.

The lectures were profusely illustrated by photomicrographs thrown upon the screen by the aid of the new and improved lantern of the McIntosh Battery and Optical Co. The lantern was operated by Dr. McIntosh, of Chicago.

The Committee on Resolutions on the death of Dr. F. H. Rehwinkel then reported the following resolution, which was carried:

*Resolved*, That the members of the Section on Dental and Oral Surgery in the American Medical Association desire to express their sorrow on the loss by death of the Chairman of this Section, Dr. F. H. Rehwinkel, of Chillicothe, O. And they would place on record their high appreciation of his character as a learned scientist and a skilful practitioner for many years, and as an honorable man in every walk of life.

On motion the Secretary was instructed to send a copy of the resolution to the family of the deceased, and that copies be sent for publication to the various dental journals of the country.

A cablegram was received from Prof. Busch, M.D., announcing the fact that a Section of *Odontology* has been organized for the Tenth International Medical Congress to be held in Berlin in 1890.

The following cablegram was ordered sent to Dr. Busch: "The Section on Dental and Oral Surgery sends congratulations for the establishment of the Dental Section, and pledges its hearty coöperation."

The Chairman's Address did not arrive as expected; it was therefore read by title and ordered printed in *THE JOURNAL* at the proper time.

On motion the Section adjourned.

### American Ophthalmological Society.

*Twenty-Fifth Annual Meeting, held at Pequot House, New London, Conn., July 17 and 18, 1889.*

#### WEDNESDAY, MORNING SESSION.

The Society was called to order by the President, Dr. WM. F. NORRIS, of Philadelphia.

DR. CHARLES STEADMAN BULL, of New York, read a paper on

#### AN ANALYSES OF 90 CASES OF SIMPLE CHRONIC GLAUCOMA,

with special reference to the effects of iridectomy upon the acuity of vision and the visual field. Detailed histories of the 90 cases were presented, and the following conclusions formulated:

In endeavoring to draw some rational conclusions from the study of 90 cases, it seems wise to begin with a quotation from Priestly Smith, to whom ophthalmologists owe so much of their knowledge of the pathogeny and pathology of glaucoma.

1. In considering the expediency of an operation in chronic glaucoma, he says, "In every case of chronic glaucoma the responsibility of advising an operation is a heavy one and should on no account be undertaken without a full explanation to the patient or his friends of the almost positive certainty of blindness on the one hand, and of the uncertainties which beset the operation on the other. Having regard to the age of the patient, the impossibility of great benefit and the possibility of a painful and accelerated progress, the prudent surgeon will only operate on the express desire of the patient to receive the only chance of benefit, however small it may be." Armed with the preceding precaution, it seems to be our duty to operate in cases of chronic progressive glaucoma, and the earlier the better.

2. If the disease in a given case seems to be stationary and is still in the primary stage, and if it be possible to test the vision and the visual field at short intervals, delay in operating is permissible, but a weak solution of eserine or pilocarpine should be used daily, merely as an aid in controlling the course of the disease. The examination of these patients should be at short intervals and should invariably include tests for visual acuity and the careful examination of the visual field.

3. If the disease exists in both eyes, but with useful vision in both eyes, the eye in which the

disease is the more advanced should be operated on without delay, and the surgeon will be guided in his treatment of the fellow eye by the result of the operation on the first eye.

4. To insure the best result the incision should be made well into the sclerotic with a narrow cataract knife or a broad lance knife, and the entire iris from one end of the incision to the other should be carefully torn or excised from its insertion.

5. The most carefully performed iridectomy by skillful hands is sometimes followed by rapid loss of what sight still remains, sometimes partial, but, unfortunately, sometimes total.

6. A successful result is, in the majority of cases, more likely to follow the operation if it is performed early in the course of the disease, but the maintenance of the existing degree of vision even in these cases is not invariable.

7. As regards the question of symmetry, it is probable that in the large majority of cases, probably as much as 80 per cent., the disease is sooner or later present in both eyes, and a careful study of the cases seems to establish the fact that there can be no specific interval of time which insures the second eye against an attack.

8. If the patient is old and feeble and one eye still free from disease for a year or more after the other eye has become affected, it may be considered prudent to avoid an operation on the affected eye, as it is probable that the unaffected eye may remain free during the remainder of the patient's life.

9. The condition of the field of vision is no constant guide either in forming a prognosis as to the progress of the disease or in deciding as to the time of operation.

10. The acuity of vision bears no constant relation to either the success or failure of the operation.

11. The anterior chamber is usually shallow, is occasionally entirely absent, but is often apparently normal in depth. The condition of the chamber gives no reliable hint as to the state of the vision or the visual field, nor any indication as to prognosis.

12. The appearance and motility of the iris appears to have some bearing upon the prognosis, though perhaps not to the extent believed by Nettleship. The latter states that in the cases in which the iris reacts rapidly to eserine the operation proves successful. This has not always been the experience of the reporter, but in the majority of the cases in which eserine caused rapid contraction of the pupil, the visual acuity was fairly good and the field was not seriously limited.

13. The depth of the excavation in and the color of the optic disc seem to have no close connection with the defective vision or with the limitation of the visual field, nor did they offer any

constant guide as to prognosis or to the effect of operation upon the progress of the disease.

14. The condition of the intra-ocular tension is a very uncertain guide in deciding the time for operating. It may be normal or increased, or even diminished. It does not even seem to bear any constant relation to the degree of visual acuity, or to the state of the visual field. The steady maintenance of the increased tension, however, without any diminution, almost invariably indicates the necessity for an immediate operation, and this necessity is especially indicated if the tension is continually on the increase.

15. The health and age of the patient exert a decided influence upon the effect of the operation. Any marked evidence of senility is distinctly unfavorable to operation.

DR. H. KNAPP, of New York: During the past nineteen years I have operated on 670 cases of glaucoma, 226 of which were cases of chronic glaucoma. I think that the prognosis may be a little more favorable than has been indicated by Dr. Bull. I have had four cases in which malignant disease followed operation for chronic glaucoma. I do not agree with the author as to the advisability of the continued use of pilocarpine or eserine in those chronic cases where operation seems doubtful. I advise its use when there are recurrent symptoms. In prognosis I am guided a great deal by the condition of the iris. My operations have been done with the lance-shaped knife. I consider it of great importance to carefully reduce the edges of the coloboma, not only by external pressure, but also by the use of the blunt probe. I am also careful not to make the operation too peripheral. Peripheral wounds are more liable to cystoid scars.

DR. EMIL GRUENING, of New York, read a paper on

#### IRIDECTOMY IN GLAUCOMA.

The speaker classified the different forms of glaucoma under the following heads: 1. Acute inflammatory; 2. Chronic inflammatory without visible degenerative changes in the iris; 3. Chronic inflammatory glaucoma with visible degenerative changes in the iris; 4. Simple glaucoma; 5. Intermittent glaucoma, and described cases illustrative of these different varieties.

DR. S. O. RICHEY, of Washington: I do not believe that simple chronic glaucoma is to be entirely a local affection. I think that it is a local expression of a cause to be looked for in the nervous system. I have used eserine with satisfaction in the early stages, but I support it by galvanism applied to the cervical ganglia. In some cases this will enable us to avoid operation.

DR. SAMUEL THEOBOLD, of Baltimore: I have met with one case in which an attack of pronounced acute glaucoma was cut short by the use of eserine.

DR. C. S. BULL, of New York: Eserine is frequently used in too strong solution. A solution of half a grain to the ounce may cause iritis after a single instillation. I never use a stronger solution than this. I often use one as weak as one-tenth of a grain to the ounce.

DR. B. ALEX. RANDALL, of Philadelphia: I can confirm the remarks in regard to the value of weak solutions. In one case of severe absolute glaucoma a solution of  $\frac{1}{8}$  grain to the ounce was entirely successful in relieving the pain. It has been used steadily for three years with no recurrence of the severe symptoms, and without the intervention of any inflammatory trouble.

DR. S. P. RISLEY, of Philadelphia: In experimenting with weak solutions of eserine, I have found that a distinct effect was experienced from a solution as weak as one-thirtieth of a grain to the ounce. If this was applied three times a day, it would in two days cause distinct browache. I have seen benefit from weak solutions where stronger solutions failed to give relief.

DR. HENRY D. NOYES, of New York: One point to which my attention was called many years ago is that in certain instances of evident glaucoma with a large amount of refractive error, it has seemed that the aggravation of the glaucomatous disease have been dependent upon the accommodative strain. In operating I have gradually withdrawn from the external peripheral place of incision. I prefer to come closer to the border of the cornea than some do. This involves less risk and is easier of performance.

DR. SAMUEL THEOBOLD, of Baltimore: My experience tends to convince one that astigmatism, and particular astigmatism against the rule, is frequently the cause of glaucoma.

DR. ARTHUR MATHEWSON, of Brooklyn: In one case of glaucoma in which iridectomy had been done without asserting the progress of the disease, a large injection of strychnia caused a decided improvement of vision which continued. I have used it in other cases with good effect.

(To be concluded.)

## FOREIGN CORRESPONDENCE.

### LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

*Prof. Bouchard's Mixed Method of Treating Typhoid Fever—The Pernicious Influence of Artificial Feeding on Young Children—Dr. Du Castel on the Antiseptic Treatment of Bleorrhagia—Injections of Carbolic Acid in the Treatment of Carbuncle—Soap as an Antidote for Carbolic Acid.*

Professor Bouchard has a mixed method of treating typhoid which consists in the application, within certain limits, of antithermic and general antiseptic. General antiseptic is obtained by

mercurial preparations. At the onset only of the fever, during four days, the patient takes 20 pills of 2 centigrams of calomel per day. Balneotherapy is prescribed as follows: As soon as the rectal temperature passes  $40^{\circ}$  C., cold baths, to the number of eight in the twenty-four hours, should be given. These baths should maintain the body at a temperature of from  $37^{\circ}$  C. to  $37.5^{\circ}$  C. If these baths do not sufficiently lower the temperature, the sulphate of quinine should be prescribed. This medicament, according to the experiments of Chantemesse and Vidal, is an excellent microbicide. The dose at the commencement should be pushed to 2 grams in the twenty-four hours. This will be gradually diminished, until a temperature of  $37^{\circ}$  C. in the morning, and  $38^{\circ}$  C. in the evening is obtained. As regards intestinal antiseptics, M. Bouchard gives the preference to naphthol A, the antiseptic power of which acts more especially on diatheses or leucomaines, products of microbial excretions, and the toxicity of which is altogether nil, even at 5 grams per day. The following is M. Bouchard's favorite prescription: Naphthol, salicylate of bismuth, of each, 5 grams to be divided in to ten powders, one of which is to be taken every hour. According to the author, the results of this mixed treatment are most satisfactory. It responds to all the indications.

Professor Bouchard vaunts the application of naphthol in the treatment of that loathsome affection called bromhidrosis. He prescribes it in the form of a solution composed of 1 gram, 50 centigrams of naphthol, and 100 grams of alcohol. He affirms that the foetidity of the sweating of the feet disappeared after a few applications of this solution.

The pernicious influence of artificial feeding on the health of young children, is well known. A statistical report, published in Berlin by M. Richard Boeckh, and which formed the subject of a report by M. J. Bertillon to the Society of Public Medicine, shows that the mortality of infants brought up by the bottle is six or seven times higher (all things being otherwise equal) than that of those nourished by their mother's breast.

This statistic proves that neither the age of the children, nor their legitimate or illegitimate connection, nor the easy circumstances of their parents could explain the difference between the mortality of infants brought up by their mother's breast, and that of those brought up by the bottle. The considerable difference between the two categories of infants (7 and 45 per 1,000 living of each category), is entirely due to the difference of alimentation. It proves also that if the mortality of illegitimate children, at Berlin, is in general double that of legitimate children, it is owing to the fact that the illegitimate children are, more often than the legitimate children, brought up by the bottle.

The opinions of Dr. Du Castel as expressed in a note read before the Société de Médecine Pratique on the antiseptic treatment of blennorrhagia may be resumed as follows: Antisepsy has always for result the maintenance of the urethra in this state of asepsy, which modern medicine seeks to obtain in every cavity which suppurates, as favorable to the cure of suppuration. In a certain number of cases, the antiseptic treatment produces a cure remarkably rapid. It is only in exceptional cases that antisepsy well conducted does not produce a prompt improvement of the inflammatory accidents, and a shorter duration of the acute stage. Antisepsy, practiced early, diminishes the chances of the propagation of the blennorrhagia to the posterior part of the urethra, and renders vesical, prostatic and testicular complications more rare. The following are the antiseptic agents employed in these cases: 1. The sulphate of quinine at 1 per cent., the permanganate of potash at  $\frac{1}{1000}$ , the bichloride of mercury at  $\frac{1}{1000}$ , and the biniodide of mercury at  $\frac{1}{1000}$  may be utilized, in the form of injections, in the treatment of acute blennorrhagic urethritis, and applied at the commencement of the malady. Momentary contraindications may be met with only in cases of local complications. 2. These agents, which, of themselves, constitute the whole treatment, are superior to balsamic remedies and to all of the procedures of the classical method, as regards rapidity and innocuousness of effects. 3. The preference should be accorded to the bichloride, and perhaps to the biniodide of mercury, the value of which can only be settled by experience.

MM. Arnozan and Lande have cited in the *Journal de Médecine de Bordeaux*, two cases in which injections of carbolic acid had given them very remarkable results in the treatment of carbuncle. In one case in particular, in a woman æt. 65 years, affected with an enormous carbuncle in the back, and the patient appearing to be in a hopeless condition, the authors injected into the cellular tissue of the periphery of the zone inflamed 5 grams of a solution composed as follows: Glycerine, distilled water, of each 15 grams, crystallized carbolic acid 3 grams. These injections were made in five points circumscribing the inflamed region. They represented a total dose of 50 centigrams of pure carbolic acid. The pain caused by the first injection was very violent, but in the evening this subsided, and an evident amelioration was produced. On the evening of the next day, a fresh injection of 30 centigrams only, on three points was made. On the third day, 20 centigrams were injected. On the fourth, fifth and sixth day 10 centigrams were injected. From this moment convalescence commenced and progressed regularly. This case is interesting in more than one point of view. The patient was in a hopeless state when the subcutaneous injection

tions of carbolic acid were practiced, and it was remarkable to see the rapidity with which the accidents had disappeared. Twenty-four hours after the first injections, the amelioration was notable, twenty-four hours later, the cure of the patient was ensured. The dose at which the carbolic acid was employed equally deserves attention, for, notwithstanding the high dose of 50 centigrams, the phenomena of intoxication which followed, were almost nil. The authors conclude that this case is sufficiently encouraging to render surgeons less timid in the therapeutic applications of carbolic acid, and authorizes, in case of urgency, an energetic intervention.

The *Moniteur Thérapeutique* relates that ordinary soap, or indeed, any soap, is the best antidote for carbolic acid. It must be administered immediately after intoxication, and frequently repeated, until the disappearance of all the toxic phenomena.

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*Dr. Roger S. Tracy's Report to the Board of Health on the Mortality of the City—The Board disseminating among the People a knowledge of the Contagiousness of Tuberculosis.*

A preliminary report in relation to the mortality in this city for the year 1888, recently presented to the Board of Health by Dr. Roger S. Tracy, Assistant Sanitary Superintendent, has attracted considerable attention on account of the somewhat surprising deductions which he makes from the results of his investigations. These are as follows: "The death-rate in tenement houses is less than the general death-rate of the city. The death-rate in the large tenement houses is less than in the smaller ones. That while diarrhoeal diseases and diphtheria show a greater death-rate in the larger houses (leaving out the suburban districts, where the conditions are very different), phthisis and pneumonia show comparatively little difference; that difference, however, being in favor of the larger houses. The greatest general death-rate among persons over 5 years of age, the next to the highest death-rate from diarrhoeal diseases and pneumonia, and markedly the highest from phthisis, are in the district south of Fourteenth Street and west of Broadway. The excessive mortality in this part of the city is probably connected with the great number of old houses and the dampness of the soil. These results are much at variance with what was expected. It seems to be sufficiently established that people do not live under such extremely bad sanitary conditions in the tenements as they have been supposed to." The figures which he presents show that while in

1869 the general death-rate was 28.13 and the tenement death-rate 28.35, in 1888 the general death-rate was 26.33 and the tenement death-rate only 22.71.

The way in which Dr. Tracy reaches his conclusions is somewhat as follows: Last year the sanitary police took a census of the tenement house population of the city. The general death-rate, in the estimated population, as just stated, was 26.33, and the fact that the highest death-rate in the tenement house population is only 26, and the general tenement house death-rate being 22.71, would at first seem to indicate that the population of the city has been underestimated and the quoted death-rate is too high, or that all the deaths belonging in tenement houses had not been credited to them; or else that the death-rate is actually lower for the tenement house population than for the rest of the city. It might be that deaths which should have been credited to these tenement houses have not been so credited. The total number of deaths in institutions was 7,774; of this number the former place of residence was ascertained in 3,444 instances, and these deaths have all been credited to the houses in which they had lived. It is evident that the remaining deaths, 4,330, ought not to be credited solely to the tenement houses, as many of them are from out of town, many from boarding-houses and private dwellings, many are immigrants just arrived, and many are old people in homes and almshouses, or infants in foundling or lying-in asylums. It is a fair conclusion, therefore, that the death-rate of the tenement house population is lower than that of the remaining population.

It would seem, then, according to Dr. Tracy, that, so far as the risk of death in New York is concerned, it is better to live in a crowded tenement house than in a brown-stone mansion on Fifth Avenue. It is probable, however, that the greater part of the tenement population, if offered the opportunity, would prefer to take their chances in the Fifth Avenue mansion. There can be little doubt that some mistake has been made in estimating the existing conditions, and that the conclusion mentioned is not justified by the real facts of the case. In commenting on Dr. Tracy's statistics the *New York Medical Journal* says the tenement house death-rate is perhaps given so low because of the inordinately high estimated tenement population; and, of course, the higher the error in an estimated population, the lower must the rate of mortality fall. In the statistics given the total population of the city is placed at 1,526,081, and the tenement population at 1,093,701 in 1888, while in 1869 the total population is placed at 894,419, and the tenement population at 468,493; showing an increase of 625,209 in the tenement population in twenty years. "In other words, if Dr. Tracy's figures are correct," says the *Journal*, "the increase has been almost wholly

in the tenements; the private house classes have grown only 6,453 in twenty years, or only 323 per annum. This is incredible; there have been thousands of houses put up in that time, to say nothing of the great number of beings that fill them. The better, or well-to-do, class, has not been stationary. Stated proportionally, according to Dr. Tracy's data, the rate of increase has been over 133 per cent. in the one class and less than 1.5 per cent. in the other. If our point is well taken, it must be seen that a good deal of what Dr. Tracy says goes for nothing."

It is a fact that when there has been continuous hot weather for a number of days the mortality in New York often mounts up from 600 or 800 to over 1,000 deaths a week, and this increase is almost entirely in the tenement house population, being due to diarrhoeal disease in infants and young children. A reporter of one of our most reliable papers recently accompanied one of the summer corps of the Board of Health's visiting physicians in his house to house inspection in a down-town tenement district; and this is what he saw: "The street was filthy, a fact that the housewives along the thoroughfare attributed to itinerant peddlers of fish and fruit, whom they charged with hiding their refuse stuff in ash barrels. But whatever was the cause, there was engendered a nauseating stench that came up in volumes under the scorching heat of the sun. But filthy and foul-smelling as the streets are, the habitations are more intolerable in both respects. The floors of the dark hallways are covered with dirt, while the walls are grimy with dust and smoke. In these pig-pen alleys half naked children that look as though they had never had a bath in all their lives play together in a half-hearted way, without laughter and almost without smiles. They do not seem to have enough life in their pale little bodies to get up a healthy romp, if such a thing were possible in such an atmosphere. Each of these tenements has a housekeeper, who is generally unclean, unkempt and slovenly. The other women in these houses are usually of the same description as the housekeeper. They seem to have an antipathy to water in any form, and spend much of their time hanging about the doors and gossiping. The rooms in which many of these people sleep beggar description. They are small, badly ventilated, and filled with stifling, foul odors; and what makes it worse is that the apartments are overcrowded to an extent that indicates a great mortality in the event of a contagious disease breaking out." Any one at all familiar with New York tenement house life will acknowledge the correctness of this picture as applied to many districts of the city.

It is a fact, however, that during the last few years much has been done to ameliorate the condition of the poor, and especially to save the lives of the children; and there can be little doubt that

the death-rate among the tenement population has been materially diminished. Each year the Children's Aid Society and the St. John's Guild care for many thousand children, and numerous summer homes among the churches provide fresh air and country pleasures for the poor; while many lives are saved by the summer visiting corps of the Board of Health.

The Board of Health has been doing a very good work in disseminating among the people a knowledge of the contagiousness of tuberculosis and the simplest and most efficient means for the prevention of its spread. In June an able report on this subject was submitted to the Board by the pathologists, Drs. T. M. Prudden, H. M. Briggs and H. P. Loomis, and more recently ten thousand copies of a set of rules to be observed for the prevention of the spread of consumption have been printed for distribution. As this is probably the first instance in which any regulations regarding this disease have been promulgated by the public sanitary authorities, it may be of interest to append them.

1. Do not permit persons suspected to have consumption to spit on the floor or on cloths unless the latter be immediately burned. The spittle of such persons should be caught in earthen or glass dishes containing the following solution: Corrosive sublimate 1 part, water 1,000 parts.

2. Do not sleep in a room occupied by a person suspected of having consumption. The living rooms of a consumptive patient should have as little furniture as practicable. Hangings should be especially avoided. The use of carpets, rugs, etc., ought always to be avoided.

3. Do not fail to wash thoroughly the eating utensils of a person suspected of having consumption as soon after eating as possible, using boiling water for the purpose.

4. Do not mingle the unwashed clothing of consumptive patients with similar clothing of other persons.

5. Do not fail to catch the bowel discharges of consumptive patients with diarrhoea in a vessel containing corrosive sublimate 1 part, water 1,000 parts.

6. Do not fail to consult the family physician regarding the social relations of persons suffering from suspected consumption.

7. Do not permit mothers suspected of having consumption to nurse their offspring.

8. Household pets (animals or birds) are quite susceptible to tuberculosis; therefore do not expose them to persons afflicted with consumption; also do not keep, but destroy at once, all household pets suspected of having consumption; otherwise they may give it to human beings.

9. Do not fail to thoroughly cleanse the floors, walls and ceilings of the living and sleeping rooms of persons suffering from consumption at least once in two weeks.

## Expenses of Officers of Sections.

*Mr. Editor:*—The following letter is one of several, of similar import, that I have received during the last six weeks:

"N. S. DAVIS, M.D.

*Dear Doctor:*—How are the necessary expenses of the various Sections—expenses for stationery, etc.—to be met? I hope arrangements will be made for meeting them out of THE JOURNAL fund of the Association. The Secretaries of Sections have already been put to a large expense for printing, correspondence, etc.

Yours truly,

A. B., Secretary of Section."

Some of these letters came to hand a little before the meeting at Newport, when I was too much occupied to take time to examine closely the Constitution and By-laws relating to the subject, and gave for answer, that if no provision already existed for meeting the necessary expenses of the Secretaries of the Sections in executing their official correspondence, the defect could be remedied by proper action of the Association while in session at Newport.

As no action was taken upon the subject at the recent meeting, and the above letter has reached me since, I think it proper to call attention to the following clause of the Constitution [Section VI. Funds and Appropriations], "The funds may be appropriated for defraying the expenses of the Annual Meetings, including the necessary expenses of the Permanent Secretary in maintaining the necessary correspondence of the Association; for publication; for enabling the *Standing Committees* to fulfil their respective duties, *conduct their correspondence*, and procure the materials necessary for the completion of their stated annual reports," etc.

This has constituted a part of the Constitution since the adoption of that instrument, in 1847, and for the first thirteen years all the scientific and professional work of the Association was done by *Standing Committees* on Medical Education, Medical Literature, Practical Medicine, Surgery, Obstetrics, Epidemics and Hygiene, etc., and it plainly provided for defraying the expenses incurred by such committees in conducting their necessary correspondence. When, in 1860, all the work of these committees was transferred to the several *Sections*, this provision of the Constitution certainly became as applicable for the payment of the necessary expenses of the Secretaries in conducting the proper correspondence of the Sections, as it had previously been to that of the *Standing Committees*.

It would be necessary for the Secretary of the Section to keep an accurate account of such expenses and to render a bill of items to the Treasurer of the Association, which when paid would remain as a proper voucher in his hands.

Yours truly,

N. S. DAVIS,

Chicago, Ill., July 20, 1889.

## BOOK REVIEWS.

MATERIA MEDICA AND THERAPEUTICS, FOR PHYSICIANS AND STUDENTS. By JOHN B. BIDDLE, M.D., late Professor of Materia Medica and General Therapeutics in the Jefferson Medical College, Philadelphia. Eleventh Edition, Revised and Enlarged, with Special Reference to Therapeutics and to the Physiological Action of Medicines. By CLEMENT BIDDLE, M.D., U. S. N., and HENRY MORRIS, M.D., Fellow College of Physicians of Philadelphia, etc. Philadelphia: P. Blakiston, Son & Co., 1889. Pp. xix-607. Price, \$4.25.

The changes which are constantly being made in Materia Medica by the introduction of new remedies and the abandonment, partial or entire, of others, necessitates frequent revisions of the standard works of this class of books. When these are of a voluminous and exhaustive character the purchase of revised editions is often a matter of very considerable expense; but there are, fortunately, less pretentious works which serve an admirable purpose while recommending themselves to the physician, by reason of their comparative inexpensiveness. The present edition of Biddle's well-known treatise is of such a character. It is a well balanced book and is thoroughly modern. Shorn of all that is redundant in the way of botanical descriptions and explanations of pharmaceutical and chemical preparations, and presenting concise accounts of the principal physiological actions of the remedies described, it affords one most valuable and entertaining reading. It does not, of course, take the place of the cyclopædic treatises on materia medica which aim at giving complete accounts of the multitudinous experiments which have been conducted with painstaking care in the various countries of the world; it does not even tell us much of what can not be accomplished by remedies; but it does give, in concise form, the principal physiological actions and therapeutical applications of the more valuable remedies at our command. Among the newer remedies introduced in this edition we find hypnone, urethan, papaya, adonidine, strophanthus, sparteine, morrhual, iodol, lanolin and saccharin; while a new chapter has been added on the subject of antipyretics, in which the phenyl derivatives, such as acetanilide, resorcin, hydroquinine, pyrocatechin, salol, naphthaline, pyridine, kairine, thalline, antipyrin, etc., have been well treated.

PAPERS READ BEFORE THE MEDICO-LEGAL SOCIETY OF NEW YORK. Third Edition (First Series). New York: Medico-Legal Journal Association. 1889.

Casper's great work on forensic medicine is to be found in the libraries of most of those who

profess any extensive knowledge of this department. Notwithstanding its author has been dead for more than twenty-five years, age appears not to have made it the less valuable. But it is not given to all branches of science to grow old so slowly, and the wisdom of the Medico-Legal Society, of New York, in reprinting all the papers which have been read before it, is apparent. The present volume, or first series, includes papers read in the years 1868-'69-'70 and '71. In Dr. Jas. J. O'Dea's essay regarding "The Sphere, Rights and Obligations of Medical Experts," he says: "Next to slander, unreasonable expectation is the greatest foe to character." If physicians acted wisely they would insist upon drawing a sharp line of distinction between the medical witness and the medical-expert witness. Expert testimony begins where ordinary testimony ends. The expert witness does more than bear testimony to facts, he delivers opinions not only on what he himself has observed, but also on what ordinary witnesses have stated under oath.

The observation of facts, listening to their recital, weighing and classifying them after due examination, and so finally rising to a conception of the general principle of which they are the expression, constitutes the task of an expert witness. Stating this conception in appropriate language is the delivery of an opinion. According to Plato, an opinion is at best but a mean between knowledge and ignorance; and the more generally it is understood in this light, the better it would seem to be for all.

To prevent experts from usurping a power which they might be tempted to use for the benefit solely of the party calling them, it is suggested as the proper remedy that the court alone should call and examine medical experts. The author's view in this respect is supported by Prof. Ordonaux. Under the usual methods the expert is practically pledged to support the side that calls him, or if not, the council will lead or force from him an opinion in the desired direction, using all his skill to bend it to the cause for which he contends, or failing, will beat down or belittle it in the estimation of the jury. Would it be possible to reach a rational or honest opinion under such circumstances, when an opinion is at most but an approximation to the truth, often not far removed from ignorance, and should never be ventured except the opportunity be given to arrive at it in a way that is intellectually honest.

**A GUIDE TO THERAPEUTICS AND MATERIA MEDICA.** By ROBERT FARQUHARSON, M.P., M.D., Edinb. Fourth American, from the Fourth English, Edition. Enlarged so as to include all preparations officinal in the U. S. Pharmacopœia, by FRANK WOODBURY, A.M., M.D. Philadelphia: Lea Brothers & Co. 1889.

This work, well known to students and prac-

tioners, preserves the same form which has characterized it in its former editions, although it has been practically rewritten and very considerably enlarged. In the hands of its author it has been made to accord with the British Pharmacopœia of 1885. There have been seventeen omissions, and the author would gladly have excluded a greater number of useless articles which still receive official sanction. There have been 113 primary articles and their preparations added. The terminations of the names of alkaloids has been made uniform by adopting the English *-ine* and Latin *-ina*, i. e., codeine and codeina. Both the metric and apothecaries' systems are used side by side throughout the book.

The American editor has added some sixty pages at the end of the volume, including a few new non-official preparations and an Epitome of the National Formulary issued by the Committee of the American Pharmaceutical Association. The reader will look in vain for such substances as antifebrin, strophanthus, peroxide of hydrogen, salol, lanolin, naphthol, sulphonal, saccharin, and others. However, this work has made its reputation, and will hold it. It may have been prudent to leave out many of the drugs now under investigation, but we usually look for new light upon them when a new book or a new edition of an old one appears.

**SYNOPSIS OF HUMAN ANATOMY.** Physicians' and Students' Ready Reference Series. By JAS. K. YOUNG, M.D. Philadelphia and London. F. A. Davis, publisher. 1889.

This volume is one of a series, future volumes of which are to appear from time to time. The author states in the preface the object of the work, which it would seem is intended to fill a want rather more extensive than its title and character justify.

We hope that students will not depend for their knowledge of anatomy upon any synopsis of the subject; it would be a retrogressive step anything but desirable. Anatomy is a science, and the presentation of its bare outlines serves only to detract from it as such. A student who has a true scientific spirit would never be satisfied with any short or condensed presentation of this most important subject. It is unfortunate indeed for the science of anatomy that it tempts men to present it in this way. As a Synopsis of Anatomy the book is accurate and excellent, but as a substitute in the schools for other and larger works, we cannot recommend it; as a short-cut for the acquirement of a broad science we deprecate it. It may facilitate the already too rapid mode of acquiring a knowledge sufficient to pass an examination, and there are many who, not being in hearty sympathy with the scientific spirit of the profession they study, are glad to avail themselves of abridged volumes, even though

they lack the life and inspiration which no true science ever wants, and which its devotees must and always will find in it. As a work of ready reference its value depends upon its accuracy, completeness and the excellence of its arrangement; we do not hesitate to commend these.

## MISCELLANY.

**MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.**—At a meeting of the Committee, held at Pittsburgh, July 15, the following resolutions were adopted:

WHEREAS, The annual meeting of the Medical Society of the State of Pennsylvania, which convened at Pittsburgh, June 4, 1889, was adjourned until the first Tuesday of the following September, by reason of the distress and confusion caused by the flood in the Conemaugh Valley; and

WHEREAS, It is the opinion of many prominent members of the Society that a successful meeting of the Society cannot be held during the present calendar year, for many reasons, the chief of which is, that the sorrow and suffering caused by the recent great calamity still oppresses the entire community to such an extent as to interfere with an early meeting; therefore, be it

*Resolved*, That the meeting of the Medical Society of the State of Pennsylvania, which was adjourned to meet September 3, 1889, be still further adjourned until the second Tuesday of June, 1890.

**AN IMPORTANT DECISION.**—In the case of the People vs. Blue Mountain Joe, the Supreme Court of Illinois held that section 11 of the Medical Practice Act, which prohibits itinerant venders of medicines, nostrums, etc., from operating in the State, to be valid. The point was raised in the present case that this section was not covered by the title of the Act, and therefore invalid. The last General Assembly attempted to repeal the Act, it being thought invalid, but this decision sustains the Act in every particular.

**THE BRAINARD DISTRICT MEDICAL SOCIETY**, of Central Illinois, met at Delavan, Ill., July 25. An interesting meeting was held. The leading paper presented was on the "Etiology of Tubercular and Scrofulous Disease," by the President, Dr. S. T. Hurst, of Greenville. Drs. N. Holmes and A. G. Servoss were appointed essayists for the October meeting, with the topics "Hysteria" and "Intermittent Fever" respectively.

**ENCOURAGING SCIENCE.**—The Vermont Microscopical Association has just announced that a prize of \$250, given by the Wells & Richardson Co., the well-known chemists, will be paid to the first discoverer of a new disease germ. The wonderful discovery by Prof. Koch of the cholera germ, the cause of cholera, stimulated great research throughout the world, and it is believed this liberal prize, offered by a house of such standing, will greatly assist in the detection of microorganisms that are the direct cause of disease and death. All who are interested in the subject and the conditions of this prize, should write to C. Smith Boynton, M.D., Secretary of the Association, Burlington, Vt.

## BOOKS RECEIVED.

Book on The Physician Himself, and things that concern his Reputation and Success. By D. W. Cathell, M.D., Baltimore, Md. Philadelphia: F. A. Davis, 1889. Transactions of the Southern Surgical and Gynecological Association, Vol. 1. Session of 1888. Birmingham, Ala.: Caldwell Printing Co.

## PAMPHLETS RECEIVED.

A Year's Record of Seventy-five Successful Cases of Abdominal Section. By B. Curtis Miller, M.D., Charleston, W. Va. (Reprint.)

Physiological Basis of Objective Teaching. By Marshall Calkins, A.M., M.D., Springfield, Mass.

Two Suggestions for Improving the Operation of Excision of the Knee-joint for Strumous Disease. By A. G. Miller, M.D., F.R.C.S., Ed., Edinburgh, Scotland. (Reprint.)

Twelfth Report of the State Board of Health of Wisconsin for 1888.

## LETTERS RECEIVED.

Dr. N. O. Lane, North St. Paul, Minn.; Dr. S. N. Sims, St. Joseph, Mo.; Gladstone Lamp Co., New York; G. & C. Merriam & Co., Springfield, Mass.; Dr. D. B. Wise, Mt. Eaton, O.; I. Halderstein, New York; Dr. A. L. Hummel, Philadelphia; Druggist's Circular, New York; Dr. J. B. Roberts, Philadelphia; Dr. Herbert Judd, Galesburg, Ill.; Dr. T. D. Crothers, Hartford, Conn.; Dr. J. A. Blanchard, Umatilla, Fla.; Dr. J. Barton Hopkins, Philadelphia; Dr. Robt. Newman, New York; Dr. W. B. Atkinson, Philadelphia; The Levitype Co., Chicago; Dr. L. Elliot, Washington; Dr. S. M. Horton, Fort Adams, R.I.; Dr. W. B. Hopkins, Philadelphia; Dr. Walter Channing, Brookline, Mass.; Battle & Co., St. Louis; Dr. K. Meller, Lincoln, Neb.; Dr. A. F. Brock, St. Louis; Dr. C. S. Wood, New York; Dr. McPherson, New York; The Analyst Publishing Co., New York; Dr. J. F. Jenkins, Tecumseh, Mich.; Dr. Dewees, Salina, Kan.; Dr. J. V. Shoemaker, Philadelphia; Dr. J. B. Ingals, Meriden, Ia.; Dr. Harold N. Moyer, Chicago; Dr. Henry O. Marcy, Boston; Wittliff, Marsilly & Co., New York; Dr. Thomas L. Bennett, Kansas City, Mo.; Dr. William Carroll, New York; Gustave E. Stechert, New York; Dr. Henry Smith, Philadelphia; Dr. J. L. Bland, Houma, La.; Dr. E. S. Elder, Indianapolis, Ind.; The Provident Chemical Works, St. Louis; Dauchy & Co., New York; Rees Printing Co., Omaha, Neb.; Dr. H. H. Powell, Cleveland, O.; Dr. L. S. King, Washington; Dr. Joseph E. Root, Hartford, Conn.

## Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from July 27, 1889, to August 2, 1889.

Capt. William R. Hall, Asst. Surgeon, is granted leave of absence for ten days. Par. 5, S. O. 80, Hdqrs. Dept. of Dak., July 27, 1889.

Capt. Samuel Q. Robinson, Asst. Surgeon U. S. Army, leave of absence for two weeks granted by par. 11, S. O. 165, from these Hdqrs., is hereby extended ten days. Par. 8, S. O. 172, Hdqrs. Div. Atlantic, July 30, 1889.

By direction of the Secretary of War, so much of par. 1, S. O. 159, A. G. O., July 12, 1889, as directs Capt. Louis Brechemin, Asst. Surgeon, to return to his station at the close of the encampment of the Illinois National Guards, is amended to direct him to report in person not later than August 20, 1889, at Ft. Robinson, Neb., for duty at that place. S. O. 174, Hdqrs. of the Army, Adjutant General's Office, Washington, July 30, 1889.

First Lieut. Robert R. Ball, Asst. Surgeon, extension of leave of absence granted in S. O. 167, July 22, 1889, from this office, is further extended ten days. Par. 23, S. O. 169, A. G. O., Washington, July 24, 1889.

First Lieut. H. S. T. Harris, leave of absence granted in S. O. 140, A. G. O., June 18, is further extended two months. Par. 9, S. O. 176, A. G. O., August 1, 1889.

## ADDRESSES.

### THE NEED OF DISCUSSING OPHTHALMIC SUBJECTS.

*An Address delivered before the Section of Ophthalmology of the American Medical Association, June 25, 1889.*

BY GEO. E. FROTHINGHAM, M.D.,  
OF ANN ARBOR, MICH., CHAIRMAN OF THE SECTION

It is my pleasant duty, respected colleagues, to welcome you as you commence the second decade of work in this Section. Believing that those of like tastes and pursuits can develop best by occasional reunions and interchange of views, the ophthalmologists of the American Medical Association met and organized this Section at the meeting in Buffalo, in 1878. Drs. X. C. Scott, of Cleveland, Eugene Smith, of Detroit, and Dudley S. Reynolds, of Louisville, were the originators of the movement. Dr. H. Knapp, of New York, was elected Chairman, and Dr. X. C. Scott, of Cleveland, was made Secretary. The first meeting of the Section for actual work was at Atlanta, Ga., May, 1879.

The late Dr. E. Williams, of Cincinnati, was among those who contributed papers for this meeting, and he was made Honorary President of the Section. He has been called the father of specialism in this country. He was the first man ever appointed to this special chair in any college this side of the Atlantic. He saw the need of specialism at a time when only the strong man dared to profess it, and against the advice of the majority of his friends, visited the great European cities where ophthalmology was then cultivated. After nearly three years of study with such great teachers as Graëfe, Helmholz, Arlt, Jaeger, Desmarres, Bowman, Critchet and others, he returned to this country to become the pioneer in this specialty. Of this great and good man we have been bereaved since our last meeting. He died Oct. 5, 1888, at Pittsburgh, Pa., at the age of 66. He was engaged in ophthalmic practice in Cincinnati, for more than a third of a century.

A memorial of his life and work will be presented by the proper committee to the Association at some one of the general sessions, but as his labors in this department of medicine, and in

establishing this Section of the Association, causes us to feel his loss more perhaps, than others do, it seems proper in this connection, to give this brief notice of his life, and pay this tribute to his memory.

At first it was found necessary to include with ophthalmology, otology and laryngology, and the resolution by which the Section was established, called for a change in the organization of the society, by which there was added to the five then existing Sections, a Section for Ophthalmology, Otology and Laryngology, which should be known and designated as Section 6.

For ten years the laborers in these last named specialties met with this Section, and contributed to its success. It was with much regret that we yielded to the necessity of providing more time for the reading and discussion of papers, and parted company with these esteemed co-laborers, who last year established a new Section, in which they will work for the first time during the present meeting of this Association.

During this meeting the work of our Section, will, for the first time in its history, be confined wholly to the consideration of ophthalmic subjects. From the programme placed before us, it will be shown that there is an abundance of work, and if our time is not fully occupied in profitable debate it will be our own fault. We have as many papers to be read and considered at this meeting of the Section as we have usually had before, and upon subjects of as great interest, and requiring as much attention as when our work embraced a wider range. This illustrates the fact that science grows deeper as its boundaries extend, and that a still further subdivision of labor becomes necessary in order to carry its work forward with the greatest success.

Fear has, occasionally, been expressed, that with such limited fields of labor in the different Sections, the subjects introduced will become hackneyed, and lose their interest, and that discussion of them will cease to be either profitable or pleasing. But discussion was never more called for in ophthalmic subjects than at the present time. No subject should be abandoned until the ultimate truth is reached, and uniformity of views are established, however hackneyed it may seem to be. We should eschew no scientific sub-

ject as trite while any of its principles are vague and unsettled.

We shall see, as we continue the work of these meetings, that there are enough mooted questions to engage all our attention, and that however extensive our wisdom or experience, it will be sufficiently taxed in attempts made to reconcile the conflicting views that may be presented.

Dr. Hotz, in his address last year, very cogently called attention to the fact that we were challenged to defend many of the doctrines that we had supposed to be very firmly established. The record of the past year has not been such as to change the state of affairs then existing. Even the value of specialism, itself, and the right of its followers to exist as a separate and independent class of practitioners, is still called in question. The qualifications that should entitle one to the right of being regarded as a specialist is also still a mooted subject. Much of value has been written upon these subjects during the past year, and the relation that should exist between the specialist and general practitioner, and also the kind of training and the qualifications that *each* should have, have been discussed. This is labor in the right direction. There are no more important subjects that can engage our attention than these, and upon their correct solution depends the future progress of ophthalmic science and art more, perhaps, than upon any others. There is no disguising the fact that the lack of sufficiently extensive mutual sympathy, and of coöperation between the family physician and the specialist is not only one of the great drawbacks to the practical usefulness of specialism, but one of the greatest obstacles to its scientific progress.

I need not enter upon a defense of specialism before this audience, composed, as it is, of those who devote themselves to the cultivation of one of the most successful of them all. You, who have limited, to a great extent, your investigations to this one small organ, know how necessary it is, to limit judiciously the field of observation in order to interrogate nature successfully, and learn from her, her secrets.

In every other department of human knowledge the necessity of such a division of labor has long been recognized. In medicine, however, it is even now grudgingly admitted, though it has furnished such abundant proof as to its value and necessity. Notwithstanding the victories won, and honors achieved by specialism, they are too recent, and too grudgingly admitted to warrant its friends in ceasing their efforts to secure for it a just recognition.

It is now more than a hundred years (1773) since Joseph Barth was appointed lecturer on ophthalmic surgery in the University of Vienna, and from this we may justly date the beginning of modern scientific ophthalmology.

Getting his first inspiration, as Fusch tells us,<sup>1</sup>

from a few lectures delivered by Wenzel, who had been called from Paris to Vienna, to settle a dispute between some physicians as to the nature of an eye affection, in the case of one of the great ladies connected with the Court of Maria Theresa, he entered upon this new field with so much enthusiasm that he soon became the most distinguished of its cultivators. He selected Beer as his assistant, and, having imparted to him his enthusiasm, he left him to continue the work he began, and Vienna soon became the centre of modern ophthalmology. Students flocked to this school from all parts of Europe. Yet so slow was the medical world to comprehend the advantage to be derived from such special study and teaching, that it was not until 1804 that the London Ophthalmic Infirmary was established, and it was not thrown open to students until 1810. In America no special instructor in ophthalmology was appointed until 1860, while in Paris, from which the kindling spark went forth, specialism was so violently opposed by the medical faculty of the University, that no teacher of this branch was appointed until 1879.

It is not two score years since in our own country, any man who attempted to limit his practice to a specialty, was ostracised by the profession, and often had to drop it and again join the ranks of the general practitioner. Nor is this spirit of opposition to specialism yet extinct or confined in its manifestation to those without influence. During the past year one of the best known medical writers in an editorial article in a prominent medical journal, revived the old antagonism, and declared that, "The specialist must become a hand-worker, plying his art under the direction of the physician, who calls to his aid the manual dexterity which the one has attained by limiting his practice to a single disease or a single operation." . . . "There is a necessity," he declares, "for an authority superior to the specialist, and the consequent limitation of the latter to a subordinate place." "Is the general practitioner, he asks, "qualified to fulfil this duty? If not, he ought to be so qualified. He *must* be if he expects to hold his proper place in the profession."<sup>2</sup>

This writer would seek to degrade all specialism to the position surgery once occupied—the position of a mere handicraft. The surgeon was at one time allowed to do his work only under the direction of the physician.

By following the lead of Hunter, however, the surgeon has achieved for himself a more independent, honorable and useful position. He decides now for himself what needs to be done, and executes it only when his own judgment dictates it. Surgeons have accomplished this by

<sup>1</sup>History of Ophthalmology in Vienna. See Med. Times and Gazette, 1886, page 692.

<sup>2</sup>Dr. William F. Vaughn, in the Philadelphia Medical Times, Dec. 15, 1885, page 204. Editorial Article on Specialism.

laying a proper foundation in the fundamental sciences, and in general medicine also, before limiting their practice to surgical cases alone. The great surgeon must first have been a good general practitioner. By adopting this principle of education, surgery, from occupying an inferior position, its followers being mere "hand-workers" under the directions of the general practitioner, has won the first place in medical rank, and now surgeons even treat their old masters often as inferiors.

The most able articles that have been written within the last year on the subject of specialism, and its relation to general medicine, have advocated a similar training for all specialists, with a view to elevating their position in the profession, and enabling them to accomplish the most for science.<sup>3</sup>

It is on this principle, it is advocated, that ophthalmology must seek to maintain its position and advance as it should. Sir Henry Power struck the key note of more recent sentiment on this point, in 1885, when he said: "If the ophthalmic surgeon of the future is to maintain the reputation and position of his predecessors in this branch of the profession, it appears to me that two things will be necessary: first, that he should possess a sound general knowledge of medicine and surgery, and second, that he should have a good preliminary training in mathematics and physics. . . . 'I hold,' said he, 'that no man should commence ophthalmic practice without long preliminary work in general or dispensary practice, or in the wards of an hospital, and I venture to dwell strongly upon it, because I think there is a tendency amongst the younger members of the profession to regard ophthalmic practice as an easy means of obtaining a livelihood, which is at once less troublesome, clean, and more satisfactory than any other branch of surgery.'"<sup>4</sup>

His remarks are worthy of consideration, and they seem to be endorsed by most modern writers, and we can do very much to advance ophthalmology by using our influence to control education so that those who come to the study of medicine shall have first received a thorough training in mathematics, physics and the physical sciences, and, that those who enter upon ophthalmic practice, shall first have had an adequate experience in the practice of general medicine and general surgery.

The ophthalmologist must answer, in some degree, to the definition some one has given of a specialist, *i. e.* "One who knows something about everything and everything about something." I commend this subject to the considera-

tion of ophthalmologists as worthy of candid discussion, and demanding a fixed policy and concert of action.

Though no great and brilliant discovery, or opening of any especially new field of research has characterized the history of ophthalmology for the past year, yet in every direction there has been patient, successful and continued labor, and it is by such, that the greatest results have always been accomplished in any department of human thought. It would take some pages of manuscript even to *name* the great army of workers, who have contributed their mite to the common treasury of advancing knowledge, and to do full justice in the way of reviewing their labors would occupy an undue proportion of your time.

Not only have the anatomy and physiology of the eye received due consideration, but almost every disease of the eye has been written upon. Not only have the special journals devoted to ophthalmology been filled with interesting matter, but the journals devoted to general medicine have teemed with valuable articles on ophthalmic subjects, in which either the investigations and experiences of the writers have been recorded, or theories of practice have been discussed. Ophthalmophotography, refraction and school work, detachment of the retina, diseases of the optic nerve, cataract, and the whole catalogue of diseases have been thus considered. Perhaps more attention than usual has been paid to the relation between eye symptoms and diseases, and diseases of the brain and spinal cord. Two papers on our programme will bring these subjects before you, and open for discussion the value of recent observations.

There is an old resolution of the Association to the effect that it shall be the duty of the Chairman of each Section to give an address setting forth the progress for the year in the department of medicine represented by his Section.

This resolution was adopted when the number of Sections was limited to four or five, and the addresses were delivered at the General Meetings of the Association, and not, as now, before the members of the Section only. This resolution has, I think, been generally disregarded during the past few years, perhaps because of the impossibility of fully complying with its requirements. Saying nothing of the numerous subjects that would require attention, and to properly discuss which would extend such an address to an unbearable length, we may ask what *one* man shall presume to decide for you what is progress and what is not? Your Chairman may think certain steps are in the line of progress, but this Section may, after full discussion, think they are retrograde.

Even a return to the old methods is advocated by some as in the line of progress, and this advocacy comes from some who are regarded as among

<sup>3</sup>See article "On the Relation between the General Practitioner and the Consultant, or Specialist," by S. Duncan Bulkley, A.M., M.D., in "Jour. of Am. Med. Association," Feb. 2, 1889, page 155, also, "The Family Physician," by Andrew H. Smith, M.D., Harper's New Monthly Magazine, April, 1889, page 726.

<sup>4</sup>Med. Times and Gazette, 1885, Vol. 3, page 161.

the leaders of thought in our specialty. This is notably true in regard to the operation and after-treatment of cataract.

It is now more than a quarter of a century since Mooren first performed iridectomy as a preliminary measure to flap extraction. The procedure was soon adopted by Von Graefe as a step of his modified linear extraction. The percentage of losses was immediately and greatly lessened, and it has continually decreased since the general adoption of that method of operating. Indeed, it has come to be regarded as one of the great advances in ophthalmic surgery. To-day we are urged to return to the old method. We are assured that iridectomy is an unnecessary mutilation, adding to the dangers and complicating the extraction. "*That the simple extraction is not only the best, but also the safest method of removing cataract.*" That the iris spread out as a *velum interpositum* between the corneal section and ciliary body, protect this, the most susceptible part of the eye, from the deleterious substances that may enter through the wound."<sup>5</sup> Statistics have been accumulating during the past year in support of these views that challenge our attention, and demand of us that we discuss anew this old and, as once supposed to be, hackneyed subject. With Carter, and the majority of others who have had experience with both methods of operating, advising the operators to retain the iridectomy as an important step in the operation, while Sweigger, Gayet, Galezowski, Wecker, Knapp and others advise simple extraction, is it a wonder if the beginner hesitates which method to try, confused and discouraged by conflicting opinions regarding the proper operative procedures to be adopted in this old operation, which in its perfection and marvellous success was considered one of the crowning operations of surgery.

But the beginner's perplexity will not end with the operation alone. One author of extensive experience<sup>6</sup> will tell him to bandage both eyes and keep his patient reasonably quiet after the operation. Another operator of large experience will tell him he need only to close the lids of the operated eye with a little plaster and allow the patient to walk about and use the other eye at pleasure. One will lead him to think that his patient may walk five miles immediately after a cataract extraction without increasing the danger.<sup>7</sup> Another of very great experience warns him not to follow such advice.<sup>8</sup> One will tell him that if any cortical matter has been left in the eye he should begin the instillation of atropine after four or five days.<sup>9</sup> Another warns him, from experience, to avoid such

instillation, as it is likely to excite a glaucomatous condition under these circumstances.

But we have not time to mention all the conflicting directions the anxious inquirer will find regarding even this one disease and its treatment. The subject of cataract is, then, not trite—it is still a live and debatable one.

Nearly as much discord prevails regarding squint and its treatment.

Although since Dieffenbach made the first operation for the cure of convergent strabismus, in 1839, the subject has been a prominent one among ophthalmologists, yet no sufficient uniformity of views exist in regard to its pathology and treatment. And when at the meeting of the American Ophthalmological Society in 1885, the subject of squint and its treatment came up for discussion, scarcely any two members had the same opinion upon the subject. This diversity of opinion existed upon all the important principles connected with the topic; whether or not there exists such a thing as *amblyopia ex anopsia*; whether it is possible to cure converged squint by the use of atropia and properly-fitting glasses; whether early operations should be performed; and whether the vision of the squinting eye is improved by an operation. Some thought the operation for strabismus was too frequently performed, and that it ought often to be postponed or not performed at all. Others thought if there was anything known with certainty it was how to treat strabismus. Dr. Roosa and others have added somewhat to the statistics and discussion of the subject since then, but none of the questions then the subject of dispute have been settled as they should be. They are all yet open to discussion, and only by further collection of statistics and thorough discussion of all the observed facts, can the truth in regard to them be arrived at and accepted.

How shall we treat hypermetropia, and the resulting asthenopia? This question seemed quite well settled more than a score of years ago by the masterly work of Donders, yet to-day no sufficiently definite rules have been agreed upon and formulated for the guidance of those who are beginners and look to the authorities for light. As a recent writer truly observed, "If we ask how much of the hyperopia should be corrected? the answers exhibit a most befogging diversity of opinion."<sup>10</sup> One so high in authority as Landolt, would allow a patient to use two-thirds or three-fourths of his dynamic refraction. Others declare from experience that this cannot be tolerated by the patient without continued asthenopia. Some will advise full correction of the Ht. Others only partially correct the Ht. Here again the greatest diversity of opinion is experienced as to how large a portion of the Ht. shall be corrected and how much left uncorrected. The rules which

<sup>10</sup> W. F. Coleman, M.D., Jour. Am. Med. Asso'n., Dec. 29, 1888, page 903.

this writer<sup>10</sup> has culled from the common text-books show the need of further discussion of even this hackneyed subject that some standard rules may be adopted, and the beginner may learn more nearly the ultimate facts from the authors, and not have to acquire them after so many doubts and mistakes in his early practice.

About twenty years ago Von Graefe announced his discovery of iridectomy as a cure for glaucoma. This disease had hitherto been regarded as incurable. For many years the profession thought we had nearly reached the ultimate facts in our knowledge of the pathology of glaucoma and the means of cure. But now those of extensive experience declare that "The pathology of this disease is still badly defined, and the therapy is not less uncertain; that neither iridectomies, myotics, nor even scleromies give any certain results."<sup>11</sup> The subject of glaucoma is not worn out. It needs further observation and further earnest discussion to get at the ultimate facts and establish the scientific principles of its pathology and treatment.

Shall we enucleate an eye during panophthalmitis? How differently are we answered. How positive are some that we ought to do so. How severely is the practice condemned by others. So imperative is the dictation that a German oculist once apologized to a medical society for having twice so operated during such a condition, though with the best success, stating that when he performed the enucleations he did not know of von Graefe's teaching on the subject. Thus while following the dictates of his reason he had unwittingly offended the dictum of authority.<sup>12</sup> Surely this subject is not only still open to discussion, but needs it very much.

Shall we enucleate or eviscerate? This is not yet settled beyond dispute, though enucleation still holds its own as not only the safest but the most speedy cure of those cases in which both are urged by their advocates for preference.

Through what medium or influence is sympathetic ophthalmia produced? The question seemed settled a few years ago, and the ciliary nerves were almost universally recognized as the medium through which the morbid condition was set up in the sympathizing eye. Recently it is claimed that the lymph channels carry pathogenic organisms from the diseased to the healthy eye, and that it is by this agency that sympathetic disease is induced. Still others believe that both these agencies are at work in the production of the disease, and if the question should be called up here the advocates of each of these theories would probably be upon their feet, each sure of his ground and asking for a hearing.

But I might go on to the most tiresome extent,

and then fail to mention all the subjects of dispute.

What few instances I have brought to notice might seem to imply that ophthalmology is one of the most unsettled branches of medicine, instead of being, as it is, the department most nearly approaching a fixed science.

In general practice we find, in the same way, the profession is urged to return to old methods, as for instance the calomel treatment for typhoid fever,<sup>13</sup> which not long ago was abandoned as a most pernicious treatment.

Not long since, a reviewer of general therapeutics, regarding this unsettled state of things, was led to make the following statements concerning that department of medicine: "To establish therapeutic facts the profession clings as with the heart and hand of one man; clings with a desperation and unanimity whose intensity is the measure of the unsatisfied desire for something fixed. Yet with what a Babel of discordant voices does it celebrate its two thousand years of experience."

"This is so well known that it seems superfluous to cite examples of the therapeutic discord; and one only shall be mentioned, namely, rheumatism. In this disease bleeding, nitrate of potassium, quinine, mercurials, flying blisters, purgation, opium, the bromides, veratria, and a host of other remedies, all have had their advocates, clamorous for a hearing; and above all the tumult are to be heard the trumpet-tones of a Chambers, 'Wrap you patients in blankets and let them alone.'

"Experience is said to be the mother of wisdom. Verily she has been in medicine a blind leader of the blind, and the history of medical progress is a history of men groping in the darkness, finding seeming gems of truth one after another, only in a few minutes to cast each back to the vast heap of forgotten baubles that in their day had also been mistaken for verities. In the past there is scarcely a conceivable absurdity that men have not tested by experience and for a time found to be the thing desired. In the present homoeopathy and other similar delusions are eagerly embraced and honestly believed in by men who rest their faith upon experience."<sup>14</sup>

The truth of some of these remarks cannot be gainsaid, but while it is granted that those who "rest their faith" upon their individual experiences alone, may be led into any conceivable absurdity it should be remembered that these experiences taken collectively furnish the material from which to glean scientific truths. It is by discussing them, and submitting them to the intellectual process of combination and comparison that those principles are deduced which constitute scientific progress.

<sup>10</sup> Galeszowski, *Med. Analectic*, Feb. 7, 1889, page 63.

<sup>12</sup> Mauthner, *Sympathetic Diseases of the Eye*, p. 160. (Webster & Spalding's Translation. Wm. Wood & Co., 1881.)

<sup>13</sup> Urged by Trube, Wuunderlich, Liebermeister and others.

<sup>14</sup> H. C. Wood, in Preface to *Therapeutics and Mat. Med.*, first edition.

Even the personal experience which this writer has referred to, as furnishing to the homœopathist facts which still further confirmed his delusion as to the efficacy of his remedies and mode of cure, also furnished the scientific physician with facts that enabled him, by discussing them and comparing them with the results obtained by other methods, to discover the natural history of many diseases, and to realize the disturbing and injurious effects of many established modes of treatment. He was thus led to realize more fully the agency of that *vis medicatrix naturæ* to which the homœopathist's success could only be ascribed, since, reasoning from known facts, the peculiar remedies of the homœopathist must be regarded as without effect. The result of this discussion of the subject was the more speedy recognition of the recuperative powers of the system, and the abandonment of injurious methods of treatment, and a consequent rapid advance in medical science and an increased success in medical practice.

In the same way a discussion and comparison of different experiences in the treatment of any form of ophthalmic disease may lead to the discovery of the important underlying principles of cure, from which must be derived that scientific practice which we aim to establish and perfect.

If this discord was to be interpreted as indicating a lack of progress it would be disheartening indeed. On the contrary it seems rather to be the natural outcome of too earnest seeking after facts. It seems with the profession as the poet declared to be true of the individual,

"Who knows most, the more he knows to doubt,  
The least discourse is commonly most stout."

At least we can console ourselves that notwithstanding all this discord and conflict of opinion on ophthalmic subjects, progress has been steadily made. When Graefe devised his cataract extraction with iridectomy he at once increased the percentage of cures very greatly. That increase went steadily on until about 20 per cent. was added to successful results, making about 95 per cent. in all. And now one of those who asks us to return to the simple operation shows us one table with 96 per cent., and another with 97 per cent. of perfect results, and in 200 cases only 2 cases (1 per cent.) of total failure.<sup>15</sup>

Why is it that after so many years we return again to simple extraction with so much greater success? What are the essential elements of this success? Is this attainable by the average operator? These are themes for discussion. So with the other subjects I have mentioned. We treat glaucoma, sympathetic ophthalmia, and errors of refraction and nearly all other ophthalmic affections with more success than ever before. What

are the elements of progress? Let us debate them.

We have indulged in a feast of statistics, and have not digested and assimilated them as we ought. It is possible that by proper discussion of these mooted subjects we can separate the truth from error, and deduce more fixed and definite principles and standard rules for our guidance in practice, and one of my objects in calling your attention to these unsettled questions is to remind you that there will be ample ground for debate in these meetings, and some, if not all, of the questions referred to will be raised for your consideration. "Try all things, hold fast by that which is good," is a safe injunction to heed, and I have no doubt that it will be faithfully observed by the members of this Section.

### THE THERAPEUTIC USES OF ELECTRICITY.

BY JOHN V. SHOEMAKER, A.M., M.D.,  
OF PHILADELPHIA, PA.

It begins to dawn upon the medical mind that the field covered by electricity is larger than that comprised by any other curative agency. That this should occur long after the whole world was disposed to accept the discovery of electricity in a form applicable to medical treatment as one which was to revolutionize medical practice, is at the first glance strange, but is nevertheless susceptible of easy explanation.

Electricity, known even to the ancients, had yet to wait until a time so modern as the end of the last century before a machine was devised to administer it even in the static form. Then, when men found themselves possessed of a force which they could for the first time generate and control, they naturally fell into confused notions about its being the vital force. Hence, when it is considered that the static form of electricity has comparatively little range in the treatment of disease, that quacks rushed forward to assert and maintain its universal curativeness, and that the sounder observation of skilful physicians discovered the untenability of the proposition, it is not surprising that when, in the early part of this century, current electricity was first generated, controlled, and applied to therapeutic purposes, electricity as a curative agent had been so discredited, that even thinkers in the medical profession were slow to believe in its remedial virtues.

On the one hand, electricity had, by those ignorant of its limitations, been lauded to the skies as a panacea; while, on the other hand, it had, by those equally ignorant of any of its merits, been decried as perfectly worthless. Empirics

<sup>15</sup> Report of the first series of One Hundred Successive Extractions of Cataract without Iridectomy, by H. Knapp. Archives of Ophthalmology, Vol. xvii, p. 73. Also second series of One Hundred Cases. Archives Ophthalmology, March, 1889, p. 10.

having absurdly imagined and claimed that electricity would cure everything, and time having proved that the claim was unfounded, the medical use of dynamic electricity came in, without trial, for a share of the obloquy which attached to the failure of static electricity to do what it should never have been alleged to be capable of performing. Yet, the therapeutic value of static electricity will stand all reasonable test, and similarly, so will the therapeutic value of current electricity. Static electricity has never been fairly tested by physicians, because extraordinary efficacy being at first ascribed to it, and then as generally denied, it lost all standing in court, while current electricity never had proper standing there, because it was discredited in advance, by the loss of faith in static electricity, for which it was no more responsible than it was for the preceding ascription to static electricity of universal virtue.

The proverb truly says that a poor workman never had a good tool, and with equal truth we may add, that a good workman can supplement a bad tool. But these cases refer to work directly wrought by the hand of man. No amount of scientific knowledge or of manual skill can supply the deficiencies of a poor apparatus. No economy could be more false than to possess and use one. To accomplish our purpose in administering electricity, the apparatus must be not only good, but in good condition. Otherwise it is worse than useless; it is a delusion and a snare to both patient and physician. Whether, therefore, the apparatus be galvanic, faradic, combined galvanic and faradic, supplied by the incandescent light current or by storage batteries, or the apparatus be for static electricity, let it be excellent of its kind, under penalty otherwise of its not accomplishing the purpose professedly sought. Makers of good electric instruments now abound in the United States; France excels in them, and even England, which was slow in having specialists in that department of labor, is now supplied.

Dr. W. R. D. Blackwood reports that both static and faradic treatment often have the effect of relieving the chest pains and the debilitating night sweats of phthisis, through the improvement which they effect in general innervation and nutrition.

Faradization of the thorax is very beneficial in spasmodic asthma and chronic bronchitis. The dyspnea of the latter is by this treatment much diminished in gravity.

Even more efficacious in the paroxysms of angina pectoris than inhalation of nitrite of amyl does prompt galvanization of the sympathetic seem to be in aborting an attack of this acute affection.

Sufferers from hay fever are so much addicted to seeking refuge in a change of climate when the season approaches when they are liable to an attack, that there has not yet been the fullest op-

portunity to experiment with electricity in cases of this disease. There is, however, reason to believe from the result of treatment which has been practiced in that direction, that hay fever can be much relieved by the employment of galvanization, administered as in exophthalmic goitre.

In exophthalmic goitre itself galvanization relieves the glandular swelling and reduces the protrusion of the eyeball. The method of application is to place the anode directly under the angle of the inferior maxillary bone (over the pneumogastric), and the cathode over the solar plexus. The current should be moderate, ten minutes at a time, at intervals of two days.

Insomnia is frequently successfully treated by general galvanization or faradization, when the use of drugs is contraindicated. General faradization just before the patient is intended to sleep has a calming effect. This is caused by the capacity of electricity to equalize the circulation and reduce the pulse without lowering its tone. The application is so simple that it can be made by a nurse or a member of the family.

Sciatica can always be relieved during its acute paroxysms by the administration of descending galvanic currents. Permanent cure of it has been frequently obtained by electro-puncture, the needle being thrust down to the nerve at one or more points along the painful portion of the nerve.

Neurasthenia is not always cured by electricity alone, although it frequently is. It will generally yield to electro-massage. This obviates the assumed necessity of the gorging which has been so general in the treatment of this complaint. The method employed is daily combined general galvanization and faradization.

Torpor of the liver is readily overcome by the faradic current.

General faradization of the abdomen every morning for a while, or if more convenient, every evening, will always provoke a movement of the bowels within a moderate time. This treatment is to be recommended far beyond that of the taking of drugs to relieve constipation, because, instead of its being followed by constipation, the effect tends to be permanent. Constant use of drugs for that prevalent ailment of constipation can thus be avoided by the employment of methodical faradization. Nothing so surely and promptly tones up the intestinal muscular fibre as does electricity, and causes the functions of the bowels to be regular.

In intestinal occlusion Dr. Larat<sup>1</sup> recommends galvanic electrization, and he reported nineteen cases before the French Academy of Medicine in which he cited six successes.

Dyspepsia in various forms receives decided relief from galvanization. Defective secretion of the gastric juice is rectified, glandular action stim-

<sup>1</sup> The Treatment of Intestinal Occlusion by Electricity. By Dr. Larat. Paris Letter to THE JOURNAL, June 15, 1889.

ulated, and the muscular tone of the stomach increased by this treatment.

Gastralgia and stomach-cramp are usually at once relieved by galvanization, as are also pyrosis and the vomiting of pregnancy. Currents not exceeding 15 milliampères are best suited to the purpose, the anode being placed on the cervical spine and the cathode on the epigastrium.

Instances have been from time to time reported of the dislodgment of impacted gall-stones by the administration of electricity. As we have no remedy for this painful malady except *dilcrea villosa*, it would be well to give electricity a fair trial for its relief.

Hæmorrhoids, although not a disease of the digestive tract, so often depend upon the blocking of the chylo-poëtic circulation, as to suggest some mention in connection with the preceding brief notice of electrical treatment as applied to the bowels. The aching attendant upon congested piles is often dissipated by placing the anode on the anus and the cathode over the liver, and passing the galvanic current for fifteen minutes, with the strength of from 20 to 30 milliampères.

The value of electrolysis in urethral stricture of the male has been incontestably proved by Dr. Newman, of New York. For that matter, contraction of any duct, such as the lachrymal canal, the œsophagus, or the Eustachian tube, is amenable to the electrolytic method. Extended clinical observation, however, is still needed to perfect these latter forms of electrolysis. For the relief of ordinary enlargement of the prostate gland, a suitable intra-rectal rheophore is required. In cases of extreme hypertrophy of the gland, the negative pole may be applied by a well-insulated needle introduced per anum, and with a current as strong as can be tolerated, say from 75 to 150 milliampères, for from three to five minutes, at intervals of three days. The indifferent electrode may be applied over the abdomen or on the thigh. In all administration of the current to a mucous membrane canal the negative pole must be used, for the positive pole would ruin the passage.

In diseases of children electricity presents excellent results. Marasmus, or general wasting and debility without loss of muscle, is readily overcome by thorough electrical treatment. In this case general galvanization should be used for its tonic effect, and faradization of the muscles employed for giving exercise to them within the lines of producing fatigue. Undue muscular exertion effected in a debilitated child would be injurious, instead of beneficial. Therefore the current should be mild, and the time of application short.

Incontinence of urine, an affection extremely intractable to treatment by drugs, is usually easily controlled by galvanization faithfully administered.

The vomiting of cholera infantum is sometimes

checked by mild faradization of the pneumogastrie.

The dyspnoea following scarlet fever, measles, and whooping-cough, and the aphonia sometimes existing as the suite of these affections, are ordinarily amenable to galvanization; and in the case of the aphonia, static electricity has proved to be extremely valuable.

Dropsy, as the suite of scarlatina, is sometimes quickly reduced by localized electrization, as is also œdema in either children or adults, provided always that it is not complicated with Bright's disease.

Faradization, which tends to relieve the engorged capillaries of the mucous lining of the bladder, is therefore often instrumental in curing cystitis in both adults and children. Incidentally it has been observed in these cases that electrization reduces the mucoid discharges from the bladder.

Galvanization has been proved to be of value in some cases of disease of the eye. Dr. C. S. Bull remarks, in the *New York Medical Journal* of April 27, 1889, that, "in traumatic anæsthesia of the optic nerve and retina, uncomplicated by any laceration of nerve tissue or rupture of nerve fibres, galvanism carefully and persistently applied has been known to produce a rapid and permanent improvement of vision when applied directly to the closed lids, and the current passed through the eyeball."

The knife-pains of locomotor ataxia are sometimes sensibly relieved by galvanization, and spinal galvanization has in some instances so greatly ameliorated the condition of the patient as to permit of his leaving his couch, to which he had previously been almost confined.

In uterine disorders electricity is almost indispensable. Extra-uterine pregnancies have been cut short by both currents, some operators preferring one, and some the other. In dysmenorrhœa intra-uterine galvanization with a strong current is of great service, while in amenorrhœa, by means of faradization through the ovaries and uterus the menstrual flow is soon established. Menorrhagia arising from relaxed uterine walls is specially relieved by faradization. When the result of villous growth of the endothelium, the employment of cauterant galvanic currents will remove the active cause of the affection.

Many eminent alienists, especially abroad, are reporting favorably on the use of galvanization in some mental disorders. Melancholia, with or without delusions, has been benefited by prolonged treatment without recourse to commitment to an asylum. Some patients, presenting delusional or monomaniacal features which had resisted routine asylum treatment, have been thoroughly restored to sanity under cerebro-spinal galvanization.

In the methods of electro-cautery we possess for many cases great advantages over those of

former surgical procedure. The galvanic loop is rapid in its operation, aseptic, and bloodless. When a current of strength sufficient to make chemical resolution is anywhere used, the operator should know that the acid goes to the positive pole and the alkali to the negative pole. Hence it is not a matter of indifference which pole is to be used for a particular purpose. In the electrolysis of a fibroid we aim at its disintegration. Hence, in that case, the needles introduced should represent the negative pole. The result is the liquefaction of the mass, and the rapidity and amount of the effect produced are dependent upon the strength of the current. If, on the contrary, we purpose arresting the hæmorrhage from a bleeding myoma, we must depend upon the action of the positive pole, the current from that pole tending to neutralize the vascularity of the part, producing coagulation of the blood.

In this connection we would remark that much inconsiderate animadversion has taken place with reference to the use of strong currents upon occasions. The question depends simply upon what is the occasion. As a general rule, currents should be used very mild, and their duration not be prolonged. But when we say that, we are speaking of currents for general practice. There are many occasions when the currents cannot be otherwise than strong if they are to accomplish their professed purpose. Such are the currents used in galvano-cautery. They are really not so efficiently strong as they appear to be from the mere mention of the number of milliampères employed, the indifferent pole diffusing the current over a vast space, and the working pole being used as a cauterizing instrument at the point operated upon.

At least brief mention should not be omitted here of the efficiency of electrical treatment in neurotic skin affections. Some forms of eczema are remarkably amenable to both galvanization and faradization. Acne is also sometimes cured by local galvanization, and at present attention is drawn to the employment of strong currents in ulcerative skin diseases. The distressing itching of prurigo is readily relieved by general galvanization or faradization.

The diagnosis of nervous diseases is greatly facilitated by electric tests. Then, the very instrumentality which has enabled us in paralysis to diagnose the extent of the disease to the best advantage, also enables us to the best advantage to treat it, if it is at all amenable to treatment.

Many nervous girls who are a burden to themselves and their families are brought into new enjoyment of life under proper electrical treatment. More treatment by electricity and less by abdominal surgery would relieve large numbers of female hysterical patients.

Epileptiform seizures and epilepsy are sometimes susceptible of amelioration by galvanization. The best way in these cases is to administer the

descending current from the vertex to the epigastrium. If convenient, the current should be administered so as to anticipate the spasm. If this be accomplished, the seizure is generally cut short or aborted. The effect of the bromides is heightened by conjoined electrization. When minor epilepsy is simply held in check by bromine, electrization combined with it has sometimes effected a cure. Chorea and allied tremor are often notably relieved by general galvanization. Cases occur in which a single muscle twitches, as, for instance, the levator labii superioris alæque nasi, for which local faradization proves entirely successful. Spasm of one or both eyelids is effectively treated in the same manner. The ordinary chorea of schools is usually cut short by strong faradization of the entire surface of the body.

When paralysis is dependent upon such central lesion as intracranial hæmorrhage, time should be given for the absorption of the clot. In from six to twelve weeks after the onset of the disease, no treatment equals faradization. Gentle faradization of the brain undoubtedly hastens absorption of the effusion on the brain. For Bell's palsy nothing exceeds in usefulness localized galvanization. The affected muscles should be picked out separately and submitted to treatment one at a time. When the galvanic current proves slow to act favorably upon the disease, static sparks may be advantageously substituted. Recovery is sometimes so prompt as to astonish even the patient.

As we remarked at the beginning of this article, early in the history of electro-therapeutics static electricity was extensively used for the cure of disease, but owing to the causes detailed, fell into disrepute. But within the last few years this form of electricity has been revived for the treatment of disease. It should undoubtedly be allowed a prominent place in peripheral nervous disorders, as there is reason to believe that deep-seated lesions are favorably reached by it through the instrumentality of reflex action.

The use of static machines for general tonic electrization is very advisable in many cases. Various hyperæsthesias and anæsthesias of the surface of the body are often amenable to static applications. Diseases resembling herpes zoster may in the beginning be amenable to this form of electrical treatment. Spermatorrhœa and other conditions of the generative organs evidencing debility, are frequently benefited by the administration of static electricity. Amenorrhœa is sometimes cured by the administration of static electricity, after other means, even including dynamic electricity, have failed. As a counter-irritant in affections of the joints, such as gout and articular rheumatism, static electrization is frequently preferable to faradization.

There is nothing concerning the medical employment of electricity in which we personally

feel more interest at the present moment than in its alleged efficacy in palliating the treatment of cancer of the breast and various other tumors.<sup>2</sup> Dr. Parsons,<sup>3</sup> of the Chelsea Hospital for Women, lately reports that he has been able to check cancer by means of electrolyzation. M. Darin also reports lately excellent results obtained from electrical treatment in the case of cancer and other tumors. If one does but for a moment reflect upon the sum of his observations of fungoid growths, whether vegetable or animal, he will perceive that their vitality seems to be of the most precarious sort, all the more precarious when the growth is morbid, when it is conditioned upon the most undisturbed circumstances to ensure continued cell proliferation and growth. It would seem, then, that as nothing is so capable as electrolysis of shattering the fundamental integrity of any tumor, it would be well to pursue the investigations referred to still further in the direction necessary to settle the question whether it is equal to the palliation or the cure of cancer.

### NEEDLESS AND ANNOYING RESTRAINTS IN EYE SURGERY.

*Read in the Section of Ophthalmology, at the Fortieth Annual Meeting of the American Medical Association, June 26, 1889.*

BY JULIAN J. CHISOLM, M.D.,

PROFESSOR OF EYE AND EAR DISEASES IN THE UNIVERSITY OF MARYLAND, AND SURGEON-IN-CHIEF OF THE PRESBYTERIAN EYE, EAR AND THROAT CHARITY HOSPITAL OF BALTIMORE.

The successful surgery of the day depends largely upon the care bestowed in the carrying out of details. Many things, little in appearance but really essential, make up the summary of successful treatment. While this applies to all surgery, it embraces eye surgery as well. The successes of to-day, which make operations upon the eye the most perfect of all surgical practice, is brought about by the great care bestowed in the preparations for the operation, the manual for its performance, and the after-treatment.

In eye surgery smooth operations cover at least 75 per cent. towards successes, so that the bad results can be partly laid to traumatism, or defective operative procedures. When an eye operation is well done the surgeon may confidently expect good results. To ensure this there are certain points upon which all agree. *Cleanliness holds the first place.* Clean instruments, clean hands, clean dressings, clean surroundings, are all of paramount importance, and should be of universal adoption. To obtain the largest per cent. of successes in eye surgery no one of these can be omitted. The necessity for asepsis and antisepsis are recognized and adopted more or

less generally and thoroughly. Our instruments must be kept sharp, as well as clean, or they will not do the nice work required of them. Putting them in boiling water before as well as after operations ensures this cleanliness, and is a good precaution which many use. The mercurial and boric acid solutions I find detrimental to delicate instruments, and hence I do not immerse cataract instruments in them. The same might be said of passing the blade of a knife rapidly across a flame. If left long enough to destroy bacteria the edge of the blade is very apt to suffer. Boiling water ensures all that is desired, with no risk to the instruments.

The washing of the eye with weak solution of mercury bi-chloride, 1 to 4000, or mercury bi-iodide 1 to 20,000, or boric acid 1 to 40, are in very general use for cleansing the conjunctival surfaces both before, during and after eye operations. Water which has been boiled is found quite as good as the medicated lotions. The eye operated upon is usually in an aseptic condition. As we desire to keep it in the same, we do not wish to impregnate the newly made wound with offending material conveyed in the water used for cleansing purposes, hence the medicated liquids in which the sponges or wiping pledgets of cotton are kept immersed while the operation is going on. This seems to be the chief protection against infection. The momentary application of these lotions to the conjunctiva can be of little service in destroying bacteria. We all do it, some going so far as to wash the face, including the eyelids, with the lotion. It is a harmless procedure, and I believe as useless as it is innocent.

Some surgeons carry antiseptic precautions to an excessive and even annoying degree. They seem to be suffering from bacterial fright, and are suspicious of the most innocent organisms. To them it is as if every man, woman and child met with on the streets of a crowded city are assassins bent upon mischief, and hence enemies. All bacteria are treated as if malignant, and are to be killed in sponges or dressings at least, by the long continued application of heat. Absorbent cotton used for dressings is baked at high temperature for hours, and then kept in air-tight jars which have been equally sterilized by long exposure in hot ovens. This seems to me a useless precaution from over-zeal, the more especially when I see unwashed hands manipulate the excessively prepared dressings. That bacteria exist and are omnipresent no one now questions; but that they are always bent on mischief only the over-zealous believe. Experience proves this to be the case, as no better results are obtained in treatment by those who over-do in their excessive preparations for an operation.

*Confinement to bed for eye operations* is another practice often annoyingly pressed to the discom-

<sup>2</sup>"On the Treatment of Uterine Tumors by Electricity," by Thomas Keith, M.D., LL.D. *The British Med. Jour.*, June 8, 1889.

fort of the patient. The eye is an isolated organ not easily influenced by the movements of the body, and therefore to a great extent independent of them. To restrict the movements of the arms and legs, and even of the jaws, because the eye has received a wound at the hands of a skilful surgeon, when such restraints are not practiced should the eye have been accidentally wounded by some crude cutting material, is inconsistent, to say the least of it. It is about as rational to stop the eye from moving because the arm is broken, as to restrain the legs because the eye is cut. The confinement exacted by some surgeons with patients who have submitted to eye operations at their hands, is cruel, the more especially as the experience of others has shown these restraints to be useless, always annoying, and in some cases injurious. I have seen a patient confined to bed because an eye muscle had been advanced. Confinement to the house in such cases is bad enough. My advancement cases walk the streets unbandaged from the moment of operation, and I secure excellent results. Why should I therefore confine them? Up to within a few years nearly all eye operations were considered proper cases for bed treatment. At the present time I am glad to know that the list of such is being freely cut, with the promise of making it eventually very small.

In my own work I use bed treatment to a very limited extent, and never make it compulsory. For the day of operation, especially if chloroform has been used, patients find the bed the most comfortable place, but after the first night they may follow their own inclinations as to its continuance. I presume it is generally conceded that lid operations, neurotomies, enucleations and muscle sections need not be cases for bed treatment. In this list I put iridectomies and cataract extractions. For the past three years my cataract patients have not been put to bed, and I have yet to see any injury from the enjoyment of this liberty. From the operating chair they walk to their chambers, and use the bed or not, as they feel inclined.

Another annoying restraint which is gradually giving way to a more enlightened experience is the use of the *dark room* in the after-treatment of eye operations. When an eye has sustained injury either by accident or at the hands of the surgeon, the common habit is to confine the patient to a dark room while undergoing treatment. With the people this is an all-pervading desire, and it is acquiesced in by the majority of physicians. Notwithstanding all of which it is a bad practice. A simple rule, and in my experience a very safe one, is to allow the patient to enjoy any degree of light which is not offensive to the eye. *If light is not annoying it will not be injurious.* By accepting this law of nature for our guidance the use of a dark room will be found very limited in eye surgery. Before I knew better, I also thought

it my duty to do as I saw others do, shut out the light of day and use candle light for all inspections. I could not find curtains dark enough to exclude all the light that I desired to shut out. In furnishing my hospital some years since every window in the building, wards, private rooms and passages, was completely covered with the darkest shades that I could find; and when in iridectomy and cataract cases the bandages were removed I had additional black curtains which were hung over the already too dark shades, so that the rooms were black enough to satisfy the wants of any eye surgeon. Now these funereal window dressings have all disappeared, and with them the dark shades. Experience has slowly taught me that the theory was wrong and the practice bad. My desire now is to exclude harsh light only, and especially to avoid all sudden transitions. My patients are treated in moderately lighted rooms and are allowed to take all the light that they can bear with comfort, only the eye operated upon being closed. To those who will try the experiment it is surprising to find how much light can be comfortably borne by the majority of eye patients, for their own advantage and that of the attendants.

I have startled some of my specialist friends who use the candle much too freely, when I took them into an ordinarily lighted room to examine a cataract case five days after an extraction, especially when I drew aside the window shade so that under the full light of day the examination of the eye could be made more thoroughly. After watching these cases for a few days, and finding much stronger eyes than they were accustomed to see under the dark room treatment, they have left me with the intention of becoming, as they say, more venturesome in the future.

*Another annoying restraint much too freely used is the eye bandage.* To tie up an eye for disease or an accident, however trivial to the organ, is a popular device of universal adoption, and one might equally add of universal misapplication. By this I do not mean to infer that the eye bandage is to be discarded from surgical practice, for we often find it an essential factor for successful treatment. I refer to its indiscriminate use, and consequent abuse. For pressure effects we need it, and must ever use it. When it is desired simply to exclude light a better device can be found. In many cases it is applied to keep an eye quiet, which is a physiological impossibility. This delusion is carried out when an attempt is made to dress an eye recently operated upon for cataract or iridectomy by surrounding it with small discs of lint systematically and beautifully piled up until all the irregularities of the orbital surface are brought to a level. These are then secured in place by a roll of bandage for what is called equable pressure. Many years since I used to extol an elastic pad of raw cotton for filling

these indications. When pressed by a bandage the soft compress would sink down, filling up any excavatory spaces, and give as I then thought, an excellent support to the cut organ. I found these theories not sustained and I abandoned that practice.

Now the only dressing I use after iridectomies and cataract extractions is a piece of isinglass plaster. It is designed simply to keep the lids closed over the eye ball. I avoid all artificial compresses. I find the lids with their tarsal cartilages a sufficiently thick and heavy compress, a perfectly adapted splint, moulded by nature to support every part of the anterior surface of the eye ball. When the eye is closed the orbicular palpebral muscle automatically makes just the degree of pressure needed, and retains the lips of the corneal wound in perfect apposition. After operations on the front of the eye ball, a strip of adhesive plaster fills every indication for lid restraint, and it should become the universal eye dressing. It is light, simple, easily applied, comfortably worn and not easily displaced. By the action of the lid muscle it keeps up equable support. It is also transparent, so that any discharges from the eye, or any changes which the lids may take on, can be seen at the daily inspection, and the condition of the eye known without disturbing the dressing. When the object is only to close the eye, the tying up of the head by bandages, however skilfully constructed, is an annoying restraint, which patients will gladly avoid. Those who have submitted to the bandage and compresses in former cataract operations, and to the adhesive isinglass strap in subsequent ones, are loud in their praises of this simple eye dressing.

*As to the tying of the hands of patients for fear they may injure the eye recently operated upon,* I am glad to say that I have never practiced it. I deem it a needless and very annoying restraint. My cataract operations now exceed 1,800, and are being added to at the rate of over 100 extractions per year—116 for the year just closed, with only two lost eyes. To have the cut eye touched by the finger during sleep, is not an extremely rare occurrence, and that the patient should be awakened with a twinge of pain is not surprising, but I have never seen any trouble come from it in these cases in which my attention was called to the accident at the time of its occurrence. Why tie up the hands of every patient as recommended by some eye surgeons, in order to avoid this imaginary danger. The very restraint, with the loss of sleep and the restlessness which it engenders, may bring about troubles much more serious to the eye than the accidental touching of it with the finger.

Another annoying and injurious restraint is *the rigid diet* enforced after eye operations. There is an idea that in some mysterious way, not anatom-

ically demonstrated, the movements of the jaws excites corresponding movements in the eye, and therefore induces bad results upon the lips of the wound recently made in the cornea. How this notion, of the jolting of the eye by the masticatory movements of the jaws, ever secured professional recognition is very surprising, but it nevertheless shows its influence in the practice of some who feed their patients on slops for days after cataract extractions. They believe that they are following out a wise course in so doing. Their patients survive and get well. But so do also the patients of those who are not subject to this soft diet. It is said that we all eat too much, and from this standpoint a few meals the less can do no great harm. But there is another law even greater in force, which reads: "to secure the ready healing of a wound with the least degree of irritation, disturb the system of the individual as little as possible, and allow the dictates of nature to reign unmolested." Take for instance, our cataract cases. They occur usually in old people, in whom habits are strongly established. They have been accustomed to daily exercise and regular eating. To suddenly suppress in an old person these natural functions, by putting him on his back in bed, with both eyes bandaged, and on rigid diet, is not the best way to keep him healthy while the corneal wound is healing.

The following case, *excessively untrammelled during the treatment*, occurred in my practice during the month of December, 1888: Mr. M., æt. 90, a wealthy old gentleman, sent me an urgent appeal to come to his home, 600 miles from Baltimore, and operate upon him for cataract. Against my established custom, I, in his individual case, yielded to his entreaty and went to him. I arrived at his home in South Carolina at 2 o'clock in the day, and found him sitting by an open fire. He could see me dimly with the left eye. With the right eye in which he had been blind with senile cataract for nearly twenty years, he had good light perception. Within a half hour after my arrival, and with no preparation whatever, I made a smooth extraction under cocaine. The eye operated upon was dressed by the isinglass strip, and the other eye with limited sight was left open. With this eye he could still see to get about, and after the operation he resumed his accustomed seat by the chimney. The only change made in this room was closing the outer slatted blinds to keep out sunlight and drawing down the shades. It was now his dinner time. After the operation he asked for his usual meal, and with my permission he had it. When 8 p.m. came he went to bed in a contiguous room, undressing himself. In the morning he was up for breakfast. I found him in his usual seat in the parlor alongside of the fire place, a screen having been placed between him and the blaze to keep the direct rays from shin-

ing into his face. He had suffered no inconvenience from the operation, had slept well, had enjoyed his breakfast, and was in every way comfortable. I left him that day at 2 o'clock, having spent twenty-four hours with him. My instructions to his family physician, in whose care I left him, were to allow him all the latitude which I had established, and only keep his movements restricted to the darkened parlor and contiguous darkened bed-room, to let him have his usual meals, to look at the face and closed eyelids daily, but to leave the dressings undisturbed for six days; also to telegraph me for instructions should any unsatisfactory changes appear. I knew that the carefully applied isinglass plaster would hold on for a week, and therefore the doctor could not indulge a curiosity for a too early examination of the eye, which he might have done had the compress and bandage been used. The programme was carried out. In due time the strap was removed; no troubles had been discovered at the daily visits. The vision of the new eye rapidly strengthened. Such good sight was restored that at the end of four weeks by the use of a two and a half-inch glass, the old gentleman himself wrote me a long letter of thanks, and as he said to give me an evidence of his handwriting, and of his complete restoration to sight. Better results could not have been obtained had he been made to go through the most orthodox course of restraining and abstaining treatment.

### FACIAL NEURALGIA CONSEQUENT UPON PREGNANCY.

*Read before the Section of Dental and Oral Surgery, at the Fortieth Annual Meeting of the American Medical Association, at New-York, June, 1889.*

BY W. W. ALLPORT, M.D., D.D.S.,  
OF CHICAGO.

In the paper that I am about to present to this Section I propose, very briefly, to discuss the nature and causes of facial neuralgia consequent upon pregnancy.

For the term neuralgia, I have never seen a definition that exactly suited me, nor am I satisfied with any definition that I myself can make. But in a general way, it may be said that neuralgia is an acute, intermittent pain carried in irregular, and often in divergent currents through the nerves and their branches, the result of an unnatural disturbance of molecular vital forces; or, it may be said to be a nerve's expression of some pathological condition, which may be contiguous to, or far removed from, the point of expression. Pain is a nerve's expression of disease, as words are expressions of thought. It is a symptom, or an informer of disease, imploring help.

The causes of neuralgia are manifold. Among the most prominent may be mentioned sudden

changes of temperature, pressure upon any portion of a nerve trunk or its branches. This may be from a local deposit or growth of any kind; or from arterial tension by an increased volume of blood; or it may be produced by an opposite, an anæmic condition, a deficiency of blood; an impoverished condition of blood, indigestion; or, in fact, anything that produces such a disproportion of the standard constituents of the blood as will disturb nutrition, or by an impairment, or decay of tissues. Upon this latter point Anstie says: "Amongst the neuralgias that are the most *absolutely* agonizing, are those which occur under circumstances of impaired nutrition incident to bodily decay," and especially is this so, when it occurs at parts at the peripheral end of the nerve.

These are by no means all of the causes of neuralgia, but I have named enough for the object I have in view, namely: to show that facial neuralgia due to pregnancy, is not due, as is generally supposed, from reflex pain, caused by disturbances in the uterus, or from pressure upon nerve trunks in its immediate locality, by the increased weight of this organ during the period of gestation.

It is a fact, I believe, that women while in this condition, suffer more from neuralgia in the upper than in the lower extremity. If this be so, there must be a reason for it; and it can hardly be from *weight* pressure, of the uterus, for were this the cause of neuralgic pain, we should naturally look for its prevalence in the lower rather than the upper extremities, while in fact, it is in the face, cranium and teeth that it is most frequently manifested. Then, too, it is a long way and a very circuitous route from the uterus to the branches of the fifth pair of nerves in the face and its surroundings, and it is difficult to see why these, rather than other nerves of the body, should be most frequently selected for reflex pain from uterine irritation, or pressure.

Although there are exceptions to the rule, I think it is an admitted fact that, while there is usually an increased volume of blood in women in this condition, the increase is in its white, rather than its red corpuscles, its life-giving properties. At the very period in a woman's life when it would seem to be most important that the proportion of life-giving properties of her blood should be the richest, it generally seems to be the poorest. When her system is called upon to sustain, in addition to her own, a new life, her blood is deficient in the life-giving properties to properly nourish her own body, to say nothing of the child she is to bear. The superabundance of serum in her blood may make her plump and full, yet she is usually pale, evincing a lack of vitality, or proper tissue nourishment.

Another important fact, bearing on the point in question, is that all below the diaphragm is in a constant state of venous hyperæmia, while that above is in a constant state of arterial hyperæmia,

and arterial tension with its muscular expansion and contraction is always a fruitful source of nerve irritation and pain. This is doubly true when the arterial hyperæmia occurs in organs like the mouth, where among the teeth there is almost always some pathological condition present.

Then, too, it is a well known fact that during the period of gravidity, most women are troubled with irritability of the nerves of the mucous membrane of the stomach; so much so that, at times, it is difficult for them to retain a sufficient amount of food for proper nourishment. It is much easier, as well as more rational, to conclude that facial neuralgia in pregnancy is reflected from the nerve irritation of the stomach, rather than from the uterus, for irritation of the stomach, or indigestion, is a well-known cause of this symptom. Neuralgia in the lower part of the abdomen, the inguinal regions, etc., is not uncommon in non-pregnant women. In pregnant women, however, these neuralgias are said to be seldom seen. If the neuralgia of pregnancy were a uterine reflex, its *locale* would naturally seem to be near to the uterus rather than distant from it, as in the prevalent facial neuralgia of this condition. In fact, the entire upper portion of the alimentary canal, including the mouth, is usually in an irritable condition, while the lower part is apt to be in a sluggish and torpid condition.

In a majority of cases the sweat glands of pregnant women are found to be in an abnormal state of functional activity; of course the face does not escape this condition, and no one need be told that with its almost constant exposure to atmospheric influences, the nerves of the face are particularly liable to those atmospheric impressions that are always productive of those molecular changes peculiar, or essential, to nerve pain.

Gingivitis is another source of irritation to which these subjects are peculiarly liable, the majority not escaping it. Such is the nervous and vascular connection of the gums with the pericemental membrane, that the disease usually extends to the latter organ, and it not infrequently happens that the entire denture becomes not only loose, but the pressure on the teeth produces acute pain consequent upon severe inflammation in the pericemental membrane. This membrane, in every way, presents the hyperæmic condition that we would expect to be productive of reflex nerve pain. Besides this, the swollen condition of the membranes surrounding the apical foramen of the tooth so strangles the vascular and nerve supply of the tooth as to seriously interfere with their functions, and must, therefore, produce irritation at the nerve peripheries. Consequent upon this, as well as from other causes, proper nourishment of the tooth structure is cut off, and the tooth is not only rendered more liable to irritation and decay from the action of external agents, but such starved condition and retrograde metamorphosis

of the nerve fibrils of the tooth structure is established, as to be prolific of the agonizing neuralgia spoken of by Anstie, which occurs under circumstances of impaired nutrition incident to a wasting of tissue or bodily decay.

## INSANITY PROCEEDING FROM THE COLON.

*Read before the Chicago Medical Society, July 15, 1880.*

BY HAROLD N. MOYER, M.D.,

LECTURER ON PHYSIOLOGY, RUSH MEDICAL COLLEGE, CHICAGO.

The term "reflex" as applied to certain pathological conditions has been so often misused, and such erroneous conceptions have been formed under this all-embracing title, that we confess to a dislike of the term and only consent to use it in its most restricted sense. One has only to refer to the vast number of surgical procedures relegated to oblivion, to emphasize the erroneous conceptions formed regarding the reflex nature of some nervous disorders; clitoridectomy, circumcision, even castration, and lastly oöphorectomy, which we believe to be still somewhat in fashion. Scarcely a portion of the body, or organ has escaped, and the recent literature from the pens of those who devote special attention to the diseases of a single organ, is filled with cases illustrating the potency and power of the particular organ, which they treat, to cause reflex nervous disorders. The ophthalmologist, not content with his reflex headache, neuralgia, etc., has recently added epilepsy to the list, the rhinologist has appended asthma to the pharyngeal tonsil, and a homœopathic surgeon has recently begun to dilate the anal sphincter and scrape out the rectum for almost every disease from hæmorrhoids to alopecia. The colon has thus far largely escaped; not, we think, through want of importance, but solely because no one seems to have devoted especial consideration to the diseases of this organ. The "colonologist" belongs to the future.

So far as my knowledge extends the earliest writer to call attention to the colon as a reflex cause of insanity, was Schroeder von der Kolk.<sup>1</sup> It formed no mean division of his order of sympathetic insanities, only yielding in importance to the uterus and sexual parts. He regarded the trouble as a true reflex, an irritation beginning in the peripheral endings of the sympathetic nerves, propagated to the vaso-motor supply of the central nervous system, and there working disorder principally in the circulation. In these days of germs and ptomaines, a more acceptable theory to many, will be that we have, in these cases, a true auto-infection; an addition to the blood of noxious elements which, circulating through the nervous system, produce toxic effects. It is probable that both theories have an element

<sup>1</sup> Mental Disease

of truth. In some cases there may be a direct poisoning of the blood, while in others the disorders may be purely reflex in character.

Von der Kolk was himself affected with this disorder. While suffering from constipation and fatigue from overwork, hallucinations and phantasms appeared to him and continued for three days. A large clyster was administered, which was followed by a copious evacuation of foul-smelling faecal matter; immediately the hallucinations disappeared and his mind became tranquil. There are no distinguishing symptoms of this condition, but an intellectual disturbance which has its origin in this source, is said by Schroeder to be characterized by a peculiar depression of spirits, by anguish of mind, and by the patient's self-accusations of wretchedness and baseness. The disease has a very slow course, and generally the mental anguish has existed some time before the physician is consulted.

Whatever view may be taken of the basic pathology of these conditions, there can be no doubt of their etiological relations, and additional emphasis is laid upon the necessity of thoroughly investigating possible sources of reflex irritation in all functional nerve disorders. The following cases illustrate the gravity of the disturbance which may follow disease of the colon and the necessity of a more careful inquiry into the condition of that organ:

July 17, 1887, I was summoned to an adjoining city to see Mrs. G., in consultation. The attending physician furnished me with the following account: Father of patient living and well, mother died of cancer of the uterus. No trace of insanity in the family, or neurotic heredity of any kind. Her health previous to the present difficulty had been fair, an occasional cough with inflammation of the pharynx being her only illness. Menstruation appeared at 14 and was always normally performed. Married at 23, and at 25 had a premature labor, this accident not being followed by any disturbance of the general health. Present illness began about eighteen months ago and was marked by an increasing general debility, loss of appetite, decrease in weight and obstinate constipation. The symptoms did not point to a change in any particular organ. Six months later had sudden attacks of faintness occurring at irregular intervals. These attacks would begin with pain in the left hypochondrium and a sense of suffocation. Within the last six months tenderness on pressure has appeared in this region, and the attacks have become more frequent and are accompanied by vomiting. During this time she had no febrile reaction, but was nervous, excitable, and affected with morbid fears. This was substantially her condition until three months before she came under my observation, when she began to show positive signs of insanity; was restless, sleepless, and incoherent, with confusional hallu-

cinations and non-systematic delusions of a depressed and melancholy character.

Examination of the patient shows the muscles and fatty tissues wasted to the last degree. The flexor tendons of the thighs are contracted, so that the legs cannot be extended. The skin is of a dirty brown color, and covered with branny scales. Eyeballs prominent, pupils react normally. Ophthalmoscopic appearance of fundus normal. The heart, lungs, kidneys and sexual organs were carefully investigated and nothing abnormal noted. A line of superficial dulness could be made out extending transversely across the abdomen, on a level with the umbilicus, and a lobulated mass could be felt in the left inguinal region, but it could not be distinctly outlined. The temperature was normal. Pulse weak and variable from 120 to 140 per minute. The mental symptoms were substantially those which were described as existing for the past three months.

A diagnosis of an exhaustional-confusional form of insanity proceeding from a dilated and over-filled colon, was made. Large rectal injections were ordered, containing in each pint of water 2 ozs. of listerine and 1 drachm of common salt. Tonics were also ordered, with cod-liver oil inunctions, massage and general faradization.

The subsequent history was furnished by the attending physician.

July 19. Condition unchanged, absolutely refused food. Insisted that her brother had been recently killed.

July 20. First injection given, consisting of about 2 pints. The tube was passed well beyond the sigmoid flexure. In about an hour the injection came away and with it a considerable amount of faecal matter. Upon withdrawing the tube, its distal end was found to be coated with dark, waxy, adhesive faecal matter entirely unlike that which came away. After the injection the patient passed into a quiet sleep, from which she awakened after about two hours, and called for food for the first time in many weeks.

July 21. Marked improvement, pulse 100. No faecal masses came away with to-day's injection, but the tube is still coated as at first, showing that a mass is still retained. Mind perfectly clear and tranquil.

July 30. Continued improvement. Since beginning the treatment ten rectal injections have been given. Occasionally a dark, hardened faecal mass comes away.

August 14. Able to be out of bed but walks with great difficulty, owing to the muscular wasting. Mind perfectly clear, but retains only an indistinct recollection of the time of her illness. For the past two weeks her bowels have acted without cathartics, and her appetite is excellent.

November 20. No longer suffers from constipation, and her health is better than it was before her illness.

An account of a striking case of this kind was sent me by my friend Dr. H. M. Bannister, senior assistant physician to the Illinois Eastern Hospital for the Insane. The patient, a panophobic melancholic with suicidal tendencies, had refused food for months and had been fed artificially. He seemed too weak to walk and was sent to the infirmary ward, where the attendant noticed that he had no free passage from his bowels. A large injection was ordered, which freed him of an immense quantity of fæces, which he had been keeping in store and letting off by driblets. Within an hour or two, during the momentary absence of the attendant, he got up, dressed himself, broke through a window and made his escape. He eluded a very thorough search, and was only heard from some time later, when he wrote a perfectly straight letter for his clothing.

Case third was that of a young man 30 years of age, having a marked neurotic heredity. His mother is now insane. Of nervous temperament, but of previous good health and strength. He consulted me for what he termed a marked change in his character and habits. From being cheerful and contented he had lately become nervous, suspicious of his fellow-workmen, fretful, and inclined to quarrels and to take offense. These mental symptoms had been accompanied by decreasing weight, failure of strength, general debility, loss of appetite and a disinclination to exertion. An account was given of irregular action of the bowels extending over one year; at times constipation and again several watery discharges, to be succeeded by a period of inaction. A copious rectal injection relieved him of a large mass of dark, consistent, foul-smelling fæces. With this came a complete restoration of the normal mental tone.

Regarding the treatment of this condition we incline to the view expressed by von der Kolk, who says (p. 134, *ibid.*): "All remedies which act as violent irritants of the colon, the so-called drastics, only increase the tendency to stricture, they add to the sensibility of the colon, and the accumulation of blood in it, and cause watery stools, while the hard masses in the upper portion of the large intestine still remain. The disquietude, the excitement, and the uneasy feeling of the patient are thereby increased, but the strength is diminished, if these medicines are continued for any length of time; the circulation becomes more and more irregular, the radial pulse becomes small, and the limbs cool." The first case is instructive in this regard. The consulting physician in that case said the diagnosis was an absurdity because the patient had been given cathartics, causing repeated movements of the bowels, and they always made her worse, increasing the weakness and mental aberration. He incontinently withdrew from the case upon learning that the attending physician agreed with us.

In ordinary constipation where there is simple atony of the bowels, laxatives may be indicated; but where we have a true overfilling with distension of the pouches of the colon, cathartics are of little use, and may be positively injurious.

434 W. Adams St.

## MEDICAL PROGRESS.

SHOULD WE TAKE PROPHYLACTIC MEASURES FOR THE PREVENTION OF PNEUMONIA FROM A POINT OF VIEW OF CONTAGION?—By DR. CRO-NIGNEAU (Société de Méd. Pratique, Paris). About a year ago I was called to a lady whom I found suffering from pneumonia affecting the lower third of the right lung. In spite of classical treatment rigorously carried out (antimonial, alcohol, tonics, revulsives), nearly the entire lung became hepatized, and although the fever did not run very high, there was soon paralysis of the bladder with retention of urine necessitating catheterization, and paralysis of the bronchi, phenomena which, in the light of existing theories, one would ascribe to an intoxication of the entire organism by the leucomaines of Fränkel's diplococci. The patient died. Eight days afterward, her brother-in-law took to bed with pneumonia of the apex of the right lung. There was no suspicion of tuberculosis, although the patient, aged 54 years, had long suffered from catarrh, for which reason there was a *locus minoris resistentie* offered to all infectious germs. The disease ran a normal course up to the eighth day, when the patient, who was very much cyanosed, died suddenly of pulmonary hæmorrhage. I have reported these cases because I wish to propose the following questions: In view of the prevailing opinions relative to the etiology of pneumonia, do we see in these two cases, separated by an interval of eight days, affecting two members of the same family living in the same house, an example of contagion or simply one of coincidence? If the former, or if we are in doubt, should we direct the family to take the precautions of disinfection which hygiene demands as safeguards against all bacteriological affections?

M. BROCC: There is more than one variety of pneumonia and all pneumonias are not contagious. The pneumonia *a frigore* of the country does not make victims of those about the patient; the pneumonia of the city, on the contrary, is often contagious. The different varieties of pneumonia present clinical characteristics which are sharply defined and, although I do not deny the existence of the pneumococcus, we are not yet sufficiently well informed of its nature and the conditions requisite for its pathogenic development.

M. GUELPA: I dispute the assertion of M. Brocq, that there are non-contagious pneumonias; for the existence of the pathogenic microbe, be it

that of Friedländer, Fränkel or others, may always be demonstrated. In this connection I may cite the case of the servant, in M. Chantemesse's laboratory, whose saliva injected into guinea pigs always produced pneumonia.

M. WEBER: Of course the contagiousness of pneumonia is associated with a microbe; but the microbe does not develop unless the soil is favorable. In animals infectious pneumonia is frequent and taking cold favors its development. There is a pneumonia of animals to which the term "pneumonia of the stables" is applied. This is always grave and difficult to cure; it attacks animals enfeebled by previous disease.

M. DUBOISQUET: I agree entirely with M. Guelpa, so far as contagion by the intervention of various microbes is concerned. But aside from the microbe there is the question of soil, as M. Weber has so well said. During the epidemic of 1886, I attended an old man with pneumonia. His wife in turn was seized, and then the *concierge* of the house and his wife. The old man and the *concierge* were both addicted to liquor; the former died, the latter was dangerously ill. The two women, who were of sober habit, were only mildly attacked.

M. LAVAUX: During the epidemic in question, I myself contracted pneumonia. My comrades, the internes, cared for me with the greatest devotion, but not one of them had the disease. I doubt the contagious nature of pneumonia.

M. PETIT: Clinically and microbiologically it is difficult to distinguish the various forms of pneumonia, and though numberless cases of its non-contagiousness are observed, the deduction that it is never contagious does not follow. This being established it seems to me proper to always use prophylactic measures, just as it is prudent to do so in the case of tuberculosis.

M. BALZER: It is especially important to disinfect the sputum and all objects which have been soiled, for the pneumococcus may preserve its existence after the pneumonia has been cured.

M. LECERF: Not merely do pneumococci exist in the saliva of people who have been attacked by pneumonia, but they are very often found in the saliva of healthy people who have never had the disease.

M. TOLÉDANO: Is it not true that the entire course of pneumonia indicates a disease of infectious nature? The fever, the duration, the incubation, the cyclical evolution are the characteristics of all contagious diseases.

M. CRONIGNEAU: As we cannot be sure that the case of pneumonia in hand is not contagious, would it not be prudent to seek in every case to protect those who surround the patient? This was the question which I asked, and the discussion which has followed seems to me to have given an affirmative answer.—*Journal de Médecine de Paris*, June 30, 1889.

ON CONDURANGINE.—ROBERT (*Les Nouveaux Remèdes*) obtained this glucoside from the bark of the condurango. It possesses two remarkable qualities: 1. If a water solution of it is heated to 40°, it coagulates; 2. If sea-salt is added to the water solution the condurangine forms a precipitate at the bottom (in these respects it resembles albumen). It has a well-defined toxic effect upon the central nervous system. When given in small doses it imparts to the walk of an animal an ataxic character which has some resemblance to that of *tabes dorsalis*. Besides this poison seems also to have an effect upon the peripheral nerves and the muscles. Electric irritability is at first increased, but diminishes afterwards. In large doses condurangine always causes a diminution of the appetite or complete anorexia; during the beginning of the period vomiting and a great deal of salivation was noticed in the carnivora. The fatal dose is 0.02 gr. per kilo of animals in carnivora and about 0.06 gr. in herbivorous animals. Does condurangine have a specific action on cancer cells? It is well known that of late the condurango bark has been much praised as a cure of cancer of the stomach. But this remains to be proven. It is administered either through the mouth or by injection of a sterilized solution.—*Journal de Médecine de Paris*, No. 21, 1889.

THE TOXIC ACTION OF COCAINE.—Cases of poisoning have been collected by DR. A. WÖLFLE from the various Austrian, German, British, French and American journals, as follows:

1. Instillation in the connective tissue sac of 15 drops of a 5 per cent. solution. Moderate symptoms of intoxication.
2. Twenty per cent. solution. Penciling of the nasal cavity.
3. Penciling of the larynx with a 20 per cent. solution (about 5 grm.).
4. Injection of 0.06 grm. of cocaine in the gums. Very severe symptoms of poisoning.
5. Injection of 6 drops of a 20 per cent. solution in the gums. Moderate degree of intoxication, without secondary effects.
6. Injection of 0.2 (!) in a case of facial neuralgia. Severe symptoms.
7. Injection of 0.021 grm. in front of the ear. Collapse; cold sweat; improvement in fifteen minutes.
8. An injection, by mistake, of 1.25 grm. in a case of sciatica. Congestion about the head, rapid pulse, quickened respiration, nervous symptoms.
9. Injection in the nasal cavity. Aphasia and agraphia.
10. Injection of a 5 per cent. solution under the periosteum of the jaw. Severe collapse in 5 cases.
11. Four centigrams in the eyelid. A doubtful case of intoxication.

12. Three-fourths of a syringe of a 15 per cent. solution in the gums. Severe poisoning.

13. Injection of 0.75 grm. (!) in the urethra. Epileptiform convulsions, irregular heart's action, cyanosis, death twenty minutes after the injection.

14. Injection of about 0.2 in the urethra. Clonic cramps, cyanosis, rapid pulse. Patient revived in an hour. Patient suffered from epilepsy.

To these cases the author adds five others which occurred under his own observation, and from his analysis of the sum total concludes that cocaine, when employed about the head and face, is capable of producing much more serious results than when used in other parts of the body more remote from the brain. This corresponds somewhat with the observation that other agents, such for example as chloride of iron; when injected in the extremities hardly ever produce injurious effects, while injected in the face dangerous emboli of the brain not infrequently result. In all small operations on the extremities or trunk a gram of a 5 per cent. solution may be safely injected; whereas in the face, with the exception of the mouth and throat, and the hairy scalp, more than 2 centigrams should never be used.—*Wiener Med. Woch.*, No. 18, 1889.

**EXTRACTION OF NERVES.**—At the Congress of the German Surgical Society in Berlin, 1889, THIERSCH, of Leipsic, read a paper on the extraction of nerves. In order to tear out nerves, especially the trigeminus, with as little manipulation as possible and as close as can be to the base of the brain, it has been customary to grasp the nerve in its continuity in the direction of its length. In this procedure the nerves which are really grasped are drawn out, but not the branching twigs. It occurred to Thiersch to twist the entire bundle of nerves, and after a number of fruitless experiments he succeeded in constructing an instrument which is fairly well adapted to this purpose. It consists of a forceps which holds fast without cutting or slipping. One branch is concave, the other convex; these fit closely together and both are serrated, the serrations being smoothed off. In the five or six years since the writer began his experiments he has operated twenty-eight times, on seventeen patients. In five cases the supraorbital nerve was involved, in eleven cases the infraorbital, in three the lingual, in four the inframaxillary, and in one each the mental, the auricularis major, intercostalis, etc.

Horsley has operated fifteen times in cases of trigeminal neuralgia, with complete cures in about one-third of the cases. In obstinate, recurring cases he has opened the middle cranial fossa and cut through the branches of the trigeminus to the inner side of the foramen ovale. Horsley was obliged to abandon an attempt to extir-

pate the ganglion gasserii on account of hæmorrhage. He regards the diseases in question as mostly of peripheral origin.

Thiersch has repeatedly performed the operation at the foramen volurdum and foramen ovale, sometimes with trephining, but regards the operation as a difficult and dangerous one, calculated to produce functional disturbances. He has considered the extirpation of the ganglion gasserii, but has never attempted it because a portion of it is firmly attached to the dura mater. He believes that these neuroses depend generally upon peripheral changes, although he has seen cases of undoubted cerebral origin.—*Wiener Med. Woch.*, No. 19, 1889.

**EXPERIMENTS REGARDING DEATH BY HYPERTHERMY, AND THE COMBINED EFFECT OF CHLORAL AND HEAT.**—On the ground of experiments made on dogs, RALLIÈRE (Paris) arrived at the following conclusions: The body temperature may be increased to 5 or even 6 degrees Celsius above the normal if this increase is temporary and immediately followed by a cooling-off; the danger of hyperthermy lies in the duration only. Animals which have stood an overheating quite well may die within the next twenty-four hours; after the expiration of this period unfavorable occurrences are not apt to take place. If the animal has previously been given chloral the danger is incomparably greater; death often occurs sooner, at lower temperatures and with shorter duration of the effect. Often general convulsions will occur immediately after the increase of temperature, or later, within thirty-six hours; in this case the animals die with a subnormal temperature (as low as 26°), or with temperature nearly normal. Sometimes death ensues without previous convulsions. The author concludes that high temperatures or continued increase of body temperature are a contra-indication to the use of chloral. He also thinks that in administering medicine the degree of fever should be taken into consideration more than has been done so far.—*Centralblatt für Klinische Medizin*, No. 26, 1889.

**ON SYPHILITIC ARTHRITIS.**—In a résumé of a clinical lecture on this subject, M. KIRMISSON, of Paris, says: From a diagnostic standpoint the exact location of the pains and of the tumefaction at one or at several places about the joint are of vital importance. Another factor equally significant is the contrast between the oftentimes anatomical lesions and the lack of functional troubles. A patient with a tumefaction of enormous size on his knee still moves his joint with great facility. In other varieties of chronic arthritis, and especially in tubercular arthritis, such immunity is but rarely observed in the movements.—*Le Bulletin Médical*, No. 43, 1889.

## REFLEX NASAL NEUROSES.

Five years have elapsed since DR. WILHELM HACH's monograph: "Ueber eine Operative Radical-Behandlung Bestimmter Formen von Migräne, Asthma, Heufieber," etc., aroused, in those not intimately familiar with the possibilities in the case, a sense of skepticism by reason of the multiplicity and diversity of the pathological reflexes which were described as emanating from the nose. Certain forms of asthma, spasm of the glottis, cough, migraine, supra-orbital neuralgia, swelling and redness of the external nose, syncope, and epileptoid seizures, were attributed to nasal irritation, occasioned by hypertrophy of the turbinated bodies, polypus, and intra-nasal deformity. His observations were, in part, corroborative of those previously published by Dr. Daly, Dr. J. M. Mackenzie, and Dr. Fränkel, while the remaining ones have since been confirmed and supplemented by other writers.

Two essays reiterating these conditions, entitled respectively, "Cough in its Relations to Morbid States of the Nasal Cavities," and "Epilepsy Caused by Intra-Nasal Disease," were read at Newport before the Section of Laryngology and Otology of the American Medical Association, and Dr. J. M. Mackenzie, at the recent Congress of the American Laryngological Association, described similar phenomena which were excited by adenoid hypertrophy in the naso-pharynx.

The term "reflex" is, doubtless, often misappropriated, yet it has a definite significance, and the pathological reflexes which originate in nasal or naso-pharyngeal irritation and terminate in

cough, laryngeal spasm, or asthma, follow much the same pathway as the physiological reflex known as sneezing. The nasal branches of the ophthalmic division of the fifth nerve and the nasal branches of the anterior palatine descending from Meckel's ganglion which is in connection with the superior maxillary division of the fifth nerve, conduct the sensory impressions to the medulla. It is there reflected to the respiratory, pneumogastric, and other centres, whence the deep inspiration, the forced expiration, and the coincident spasm of the pharyngeal and laryngeal muscles, termed a sneeze.

This mechanism, of course, varies somewhat with the different pathological reflex acts, and in the group constituted by reflex pareses, considerable complexity may enter by implication of the vasodilators through the superior cervical sympathetic ganglion.

But nasal irritation does not in every case result in reflex phenomena. Evidently still other conditions are essential.

Certain cases are in part determined by involvement, especially of the "sensitive areas" described by Mackenzie, of Baltimore, as limited to the nasal erectile tissue and particularly to the posterior ends of the inferior turbinates, but even then the tendency to evolution of reflex phenomena varies in different individuals. Functional derangement tending toward special susceptibility of certain nerve centres, including those wrought upon by peripheral nasal irritation, doubtless determines other cases; and chronic inflammation or a predisposition to acute congestive states of particular organs, unquestionably favors the development, at that point, of the ultimate link in the reflex chain. Thus, one affected with bronchitis would suffer the more readily from asthma excited reflexly by nasal irritation, laryngitis predisposes under like conditions to spasm of the glottis, and digestive derangements to migraine. So, in the completed cycle three factors obtain: nasal irritation, super-excitable nerve centres, and a susceptible peripheral organ. But the nasal irritation is the initial link without which the peculiar reflex is not excited and to which the other factors are subservient. It is the element most easily demonstrated, most readily removed, and eradication of which will accomplish a cure.

It is, perhaps, not as specifically stated as it should be by writers, that only a considerable

number of such neuroses have a nasal origin. Identical symptoms can proceed from distal irritation elsewhere than in the nose or from immediate disease of the organ of manifestation, and nasal irregularities, being general, may confuse the diagnosis by incidentally coexisting. Emphysema and nasal polypi are not uncommonly associated, but it would be unwise to expect the mere removal of the polypi to afford complete relief of the dyspnoea consequent upon the emphysema. Nevertheless the polypi should be removed, as in this and analogous states, benefit is thereby secured to nasal function and any possible reflex nasal element is eliminated.

Occasionally the relation of cause and effect between nasal disease and its reflex manifestation becomes apparent from the general history and symptomatology. Again, the diagnosis can be made by exclusion, and more rarely, an explosion of the reflex may be induced through artificial irritation by a probe to the sensitive area. But commonly only the subsidence of the reflex act following the removal of an associated nasal lesion will amount to a demonstration.

It is certainly "unnecessary where no inconvenience is felt to restore geometrical symmetry to the turbinated bodies or to invest the lining membrane of the nose with artistic merit," but the mere coexistence of a decided pathological condition or deformity in the nose with any one of the reflex acts known, at times, to proceed therefrom, should prompt the immediate correction of the nasal fault.

#### ILEUS.

The perennial effort of the medical world to secure some definite mode of treatment for intestinal obstruction (an indefinite ailment) praiseworthy as it is futile, has again made its appearance. This time at a recent meeting of the Berlin Medical Society, through the presentation by DR. GOLTDAMMER of a series of fifty cases, occurring in his own practice which he had treated without selection and consecutively, by large doses of opium. The results obtained by such treatment, (30 per cent recovery), compare very favorably with those of laparotomy—out of 328 cases of laparotomy collected by B. F. Curtis, 68.9 per cent. mortality—and invite our mature deliberation, especially when we bear in mind the com-

mon opinion extant among surgeons as expressed by Greig Smith, quoted by Jacobson, viz.: "To acute cases there can be but one termination *death*. . . . Certainly 95 per cent. of such cases die, hence the indication is clear enough (as clear as the indication to tie a bleeding) carotid artery."

Not that we may ever hope to discover a panacea for an ill possessing, a symptom-complex that may be evoked by the most varied of anatomico-pathological conditions: from intestinal concretions to cancer, mesenteric embolism to invagination; but because by so doing we may possibly disabuse ourselves of the notion that there is but one proper course to pursue in every case, as well as reap the benefit of the new truths always elicited on such occasions. Among the latter then the above quoted opinion is not wholly true.

"Success in this department will only come when a diagnosis has first been made, at least with reasonable surety. The practice of explorative laparotomy for every case is as yet to be condemned. Our statistics can only then be made more favorable than the expectant treatment, when we have selected those cases in which there is a reasonable hope." (Jacobson).

Just here it seems fitting to emphasize the fact that 30 per cent. of all cases recovered under such palliative treatment as full physiological doses of opium may be considered to be, when combined with rigid attention to diet. Also that the post-mortem examination of those dying under said treatment were as follows, 20 per cent. cancerous, 10 per cent. old cicatricial adhesions, 14 per cent. invaginations, 6 per cent. old or new perimetritis, 12 per cent. old strictures from cicatrices, and 4 per cent. tubercular peritonitis, extensive adhesions.

If we regard as incurable by any treatment the cases of cancer, the cases of tuberculosis with adhesions, and half the cases of invagination—such are the statistics for the latter—he is to be credited with results that "must give us pause"—over 50 per cent. recovery!

In concluding he presented the following deductions, which are thoughtful if not to be commended in every case.

1. To be operated are: Cases in which an invagination is clearly to be diagnosticated as shown, by the youthful age; sudden onset; bloody stool;

absence of meteorism, possibly tenesmus; but above all a tumor.

2. In such cases of very acute inception as fail to receive benefit from the bold use of opium—7 grains in twenty-four hours—and in whom the symptoms of collapse continue after such treatment to increase. And,

3. Finally in those cases in which the opium has, for a time seemed to benefit only to have the symptoms reappear. If to these we add those which the surgical authorities are now almost unanimously agreed never to operate, (a) when an approximately correct diagnosis cannot be made; (b) when the patient is already moribund; (the statistics in the past have been spoiled by such surgery) or (c) when there is great cachexia with distention; we will not go far astray in our treatment.

As to diagnosis there is this to say: Bearing in mind that we may have all the symptoms as secondary to acute inflammatory processes; peritonitis, perityphlitis, etc., or likewise (and this without actual occlusion of the gut) in paralysis, embolus of the art. mesar. or external adhesions; that it is essentially differential, and must be made by exclusion. To do this some aid may be furnished by an effort on the part of the physician to answer the following five questions:

1. Is it mechanical or inflammatory, acute or chronic?
2. Is there a tumor palpable?
3. What is the location?
4. Is it a new growth?
5. Where was the initial pain?

1. The inflammatory ileus, (*ileus inflammatorius* of old writers) will differentiate itself from that which is of mechanical origin, by the history of fever with its concomitant symptoms of pain and tenderness, the former of a colicky, the latter of a localized character, the other systemic excitation rather than a depression. If constipation exist in the inflammatory obstruction, it is not so complete that some feces cannot be reached by enemata. Having ruled out the inflammatory form, then decide as to the acuteness of the attack. Among the acute obstructions are to be classed volvulus; invagination; incarceration; almost always affecting the small intestine, and requiring operative interference for cure. Pain in the incarceration abrupt in its onset and continu-

ous; while paroxysmal in intussusception and volvulus. The two quickly fatal, meteoric as well as meteorism, the last slow; no meteorism.

If *chronic* then we have to deal with the large intestine and carcinoma in by far the largest number of cases, though stenosis from syphilitic and tubercular origin are also factors here. How exceedingly essential however it is to differentiate between the sudden failure of compensation after a gradually occurring stenosis, and an acute obstruction, Rosenbach has recently demonstrated, making at the same time a taking parallel between this and the similar failures in other organs, like the heart, bladder, stomach, etc., where a time comes when the work becomes greater than the compensatory hypertrophy, and sudden absolute failure results.

Study the initial symptoms and prodromata!

2. Almost every case of invagination is accompanied by a characteristic sausage-shaped tumor, so much so that 70 per cent. are to be diagnosed; when we take into consideration the absence of meteorism, blood in stool, etc., with the tenesmus so characteristic. The rectum should be explored in *every case*, with the whole hand if necessary, when the tumor can usually be felt, as well as the answer to the fourth question elicited, for over 60 per cent. of the large intestine occlusions are located in the rectum and sigmoidea.

3. *Location.* Every case will be treated to a number of enemata before a positive diagnosis has been made. Knowing that the average rectum holds a pint, that  $1\frac{1}{2}$ , 2 and 3 pints are required to fill the three segments of the sigmoidea, and never more than 9 pints the colon, we can approximate the location of the obstruction if we measure the quantity of fluids injected. This should be done gradually, gentle massage of the abdomen being employed, and an elevation of syringe 6 feet (which gives 2.6 pounds pressure). Vomiting of formed feces is the only absolutely sure stercoraceous vomiting, and indicates that the location is at least below the valve. It is admitted that illy-smelling digesta come sometimes from the lower portions of the ileum.

The nearer to the pylorus the greater the suppression of urine. The *signe de Dance* is a depression in the right iliac fossa, due to the traction of an ileo-cæcal invagination, as it mounts upward and toward the mesial line.

The last question both aids in locating, as well

as from its nature determining the character of the obstruction.

A fitting conclusion to this will be the observations of R. H. Fitz, . . . "The diagnosis must be made in the first two days; the capacity of the colon determined before tympany develops. Make diagnosis by exclusion, seat by injection, variety by seat, age and antecedents. Treatment is surgical on the third day." To which we will only add, if the diagnosis *cannot* be made, *use opium. In medias tutissimus ibis.*

#### EDITORIAL NOTES.

##### HOME.

DR. W. P. MANTON, of Detroit, has received the appointment as consulting gynecologist to the Eastern Michigan Asylum.

FACULTY CHANGES.—The College of Physicians and Surgeons at St. Louis have added to the faculty Dr. Y. H. Bond, as Professor of Gynecology; Dr. Wm. Porter, Professor of Diseases of the Chest; and Dr. I. N. Love, Professor of Diseases of Children.

THE NEW YORK BOARD OF HEALTH.—The Sanitary Superintendent of the City Board of Health, Dr. Walter DeF. Day, has been compelled to resign on account of ill-health, after sixteen years of service. Dr. William A. Ewing has been appointed in his stead. Dr. Ewing has formerly had a long term of service in the Board, as Sanitary Inspector, going back after an absence of three years.

THE HOSPITAL AT BURLINGTON.—The Mary Fletcher Hospital at Burlington, Vermont, has added an ophthalmological service, with Dr. J. H. Woodward in charge. Dr. Richardson of the Visiting Medical Staff has resigned and Dr. J. C. Rutherford has been appointed in his stead. Dr. Walter Carpenter has been reelected President of the Board of Trustees.

UNIVERSITY OF MICHIGAN.—It is reported that the Professorship of Surgery in the Medical Department of the University of Michigan has been offered to Dr. Charles B. Nancrede, of Philadelphia. He is the Senior Surgeon at the Episcopal Hospital in that city.

IMPROVEMENTS AT THE PROTESTANT HOSPI-

TAL.—*The Weekly Medical Review* says: The Protestant Hospital Association (St. Louis) has recently been the recipient of some generous donations, amongst which we note the following: By Mr. and Mrs. Thos. B. Dyer, a strip of ground running along the south line of the hospital property, and which is equivalent to at least \$1000. Mr. Alex. Largue, before his decease, expressed a determination to make a bequest to the hospital of \$500. He died before he had completed his will, but his widow and son, Mr. Alex. Largue, Jr., have voluntarily paid over to the Hospital Association their proportion of this \$500. Mr. Wm. R. Pye has shown his liberality by donating \$5000. That the hospital is in a flourishing condition is shown by the fact that the want of room compels the erection of an addition and the making of alterations to the extent of \$10,000; this work is now in progress. Twenty-four new private rooms will be added.

ICE IN THE SICK-ROOM.—*The Sanitarian* says: A saucerful of shaved ice may be preserved for twenty-four hours with the thermometer in the room at 90° F., if the following precautions are observed: Put the saucer containing the ice in a soup plate and cover it with another. Place the soup plates thus arranged on a good, heavy pillow, and cover it with another pillow, pressing the pillows so that the plates are completely embedded in them. An old jack-plane set deep is a most excellent thing with which to shave ice. It should be turned bottom upward, and the ice shoved backward and forward over the cutter."

A MEDICAL INDEX.—*The Times and Register* has commenced the publication in its columns of a Medical Index which will contain a list of original articles published in exchanges, especially those of interest to the practitioner.

ALL HONOR TO HIM.—*The Albany Medical Annals* relates the following: One of the bright spots in the Johnstown disaster is furnished by a member of our profession. Among the mass of shattered humanity was Dr. Matthews. He had himself sustained the fracture of several ribs; but with the loyal instinct of the right-hearted physician he devoted himself to those about him who, with broken limbs and otherwise gravely hurt, were in need of some surgical help, besides cheering them with encouraging words. In the scattered and disjointed reports we have had but

a glimpse of this scene, but when the history of the great event is connectedly written, it is to be hoped that this episode will be found true and due honor given to the hero of it.

**BIRTH RETURNS.**—The *Medical Record* quotes the following from the *New York Herald*: Massachusetts has a new statute, which has just gone into effect, for securing a more perfect record of vital statistics. All doctors are required to report births, and for each birth reported the doctor gets a fee of twenty-five cents. No penalty is fixed for failure to report. This little fee is no great object, yet it is proper as recognizing that the State has no right to exact a gratuitous service from medical men—which it does when it calls for a whole series of certificates that must be given under penalties for failure, as with doctors in this city. The language of the Massachusetts statute is odd. It requires the doctor to report all births "at which he is present." Suppose the baby is born before the doctor gets there.

The New York County Medical Association has a special committee for the purpose of considering the certificate-grievance, with the view of securing as well more complete returns. A professional friend solemnly assures us that half his life is spent in writing certificates for life insurance, schools, judges, societies, and all kinds of health organizations. Great Britain and, we think, Germany wisely throw the responsibility of returning births upon the parents themselves. At all events, the legal opinion is that the State has no power to impose any service without providing a compensation.

#### FOREIGN.

**A NEW USE FOR FLAGS.**—The medical department of the Paris University will use a flag whenever a confinement is in progress in the lying-in wards. A blue flag indicates a simple confinement, a yellow flag a difficult labor, and a green flag that an operation may be necessary.

**FRENCH CONGRESS OF SURGERY.**—The fourth meeting of the French Congress of Surgery will be held in the large amphitheatre of the School of Medicine, Paris, from October 14 to 20. The following questions will be taken in the order of the day of meeting: 1. Results, direct and remote, of practical operation for local tuberculosis. 2. Surgical treatment of peritonitis. 3. Treatment of aneurism of limbs. Baron Larrey will preside.

Dr. S. Pozzi, 10 Place Vendome, Paris, is the Secretary-General of the Congress.

**LOW MORTALITY AMONG THE FRENCH TROOPS.**—The health of the French army is constantly improving. The death-rate has fallen to 7.58 per 1000. This is the lowest point yet reached in this army, and it is lower than has been reported concerning any other of the European forces. The troops in Tunis exhibit the highest rate of mortality, about 19.4 per 1000. The disease which figures most prominently among the causes of death has been typhoid fever, which gives about one-tenth of the admissions to the hospitals, but even in this respect the conditions show a manifest improvement.

**THE HEALTH OF THE POPE.**—The age of Leo XIII is said to be 82 years, but his health is firmer and better than it was twelve years ago when he became Pontiff. He is described as active, robust and hearty for one of even a less advanced age, and he speaks of himself in far more promising terms than he did twelve years ago, when he told his friends that it would be useless to make him Pope, for he had only a few months to live, and his appearance then did not belie his words.

**HYDROPHOBIA IN BRAZIL.**—The *Lancet* contains an abstract of the first annual report of the Pasteurian Institute at Rio de Janeiro. It comprises the data of the work performed during the first eleven months of its existence. The first patient was received February 9, 1888, between which date and January 8, 1889, one hundred and six persons were treated for hydrophobia, with only one death. Sixty-two of the patients were undoubted cases of biting by dogs having rabies. The death is reported to have been the case of a young child who was not long enough under treatment to allow of the full Pastenrian method.

**IN INDIA** the *Indian Medical Gazette* has a vigorous article dealing with the need of an Imperial Sanitary Board. A new Women's Hospital is to be erected at Kurrachee at a cost of 40,000 rupees. Calcutta will soon be provided with an Ophthalmic Hospital through the liberality of a native gentleman, Baboo Churn Lahaa. Dr. Lall Madhull Mookerjee is the President of the Calcutta Medical Society. Typhus fever is epidemic in the Rawal Pindi districts.

## TOPICS OF THE WEEK.

## OCEAN CLIMATIC THERAPEUTICS.

The following are some of the things well said by DR. ALBERT L. GIBON, Medical Director U. S. Navy, in his Address before the American Climatological Association, in June last.

First, if season, course, and destination be judiciously chosen, the invalid will obtain, on a long voyage, in a comfortable sailing vessel, *rest*—of mind and body—a condition of absolute insouciance, and relief from the cares and distractions, the daily worries and anxieties of life, the interruptions and noise and turmoil and excitements which railroads, telegraphs, and newspapers bring into the very sick-room on land.

If not so completely bed-ridden (in which case he probably ought not to go to sea at all) but that he can lie in an easy chair on deck, he will be able to breathe and bathe in an air that is barren of every impurity, and with every inspiration experience a sense of pleasurable invigoration.

If sea-sickness is not an indomitable idiosyncrasy, as I have known it to be even in captains of the navy, he will, after a few days, when he "gets his sea-legs," as sailors term it, find inexpressible delight in pacing the narrow bounds of the quarter-deck, and lengthen the hours of this gentle exercise until they become whole watches long.

Once accustomed to the motion of the vessel and of the sea, nausea will give place to appetite, which is sharpened as well for old salts as land-labbers, and the plainest food will be taken with unwonted relish, betokening improved assimilation. If care be had to overcome the usual tendency to constipation, ingestion may go on without restraint. The eagerly anticipated meal-hours become the eventful marks of the passage of time. The whilom patient eats and sleeps, and wakes to find new zest in the simple employments of the day. Rocked in the cradle of the deep, the ocean's lullaby soothes the sufferer into forgetfulness of his ills. . . .

Next to the transitory exposure to ocean climate in the course of a sea-voyage is the residence on some small mid-ocean island where there are few vicissitudes of weather, short range of temperature, and none of the physical befoulments from masses of men and animals or decaying vegetable matter. Here, even better than on shipboard, is to be found the opportunity for making ocean climatic influences available as curative measures. . . .

The therapeutic agencies which operate upon the broad ocean—rest, pure air, equable temperature and moisture, and the minimum of disturbing causes, are to be found in almost as great degree on the ocean islets, where the sound of rippling springs, the sight of fresh verdure, and the scent of earth replace the monotony of the horizon-bound disk of water.

These islets are dotted over the sea—numerous in Oceanica, where distance and rare opportunities of communication place them beyond convenient and frequent access—less numerous but easily reached in the Atlantic,

where midway between the continents they invite the weary broken down sufferers in mind and body to find rest and sweet oblivious antidote for all their ills. The Azores, Madeiras, and Canaries are the chief among these "isles of the blest." The former, especially Fayal, about two thousand miles, ordinarily a pleasant fortnight's run from Boston, offer a climate so mild, that one need hardly look for a better, were it not that the better is to be found at Madeira, and a best of all at Orotava on the Island of Teneriffe, one of the group of the Canaries—*Las Canaris* of the Spanish, the *Insule Fortunatæ* of Roman geographers, whose mountain peaks stand above the waters like tombstones in this ocean cemetery, where a continent and its millions of Atlantean inhabitants are buried.

The Madeiras are but five hundred miles from the Azores, and the Canaries two hundred farther south, so that the way is easy to that delightful spot, which Humboldt thanked God he had lived to behold—the valley of Orotava, fit garden of another Eden, where he who would begin life anew may find everything save the vice and artificialities and malefic agencies of modern civilization.

Is it not time to stop and ask ourselves whether it be not the better part to place our patients where, amid Heaven's boundless supplies, the wiser air-cells, and blood-vessels, and lymphatics may themselves select just what they most require—where pure air and water, and good food, cooked to tempt the palate with half the art in making pretty portions to please both eye and taste, shall be the tonics to regenerate the blood till it revivify the worn-out nerves, repair the wasted tissue, and set once more in healthily play the vital machinery which animates and gives the body being? Mere drugs cannot do this, and drugs needlessly, excessively wrongfully administered, can only retard it. The pharmacist may oftentimes be idle, but the therapist's task will be no lighter, for climato-therapy requires sound judgment, wise and discriminating adaptation of natural agencies, and the same watchful observation of the grade of action shown by the pulse, the condition of the organic fibre, and the state of the secretions, which are the sum of the physician's duty, however huge his pharmacopœia. If he can preserve tissue from destructive change, keep the emunctories in active play, and control the pulse's fitful beat, he may patiently bide his time for those forces to exert their power, which out of the germinal vesicle make the perfected man—out of the stomach's bole, the blood's living corpuscles, and out of these the sentient flesh and conscious brain.—*Medical News*.

## THE MEDICAL SOCIETY OF DELAWARE.

This organization dates back to 1789, and accordingly this is its centennial year. The annual address delivered by W. T. SKINNER, M.D., of Glasgow, Del., is replete with historic as well as medical interest. We would be pleased to publish the entire address as found in *The Medical Bulletin*, but must content ourselves with a few brief extracts:

"The Medical Society of Delaware is one of the oldest institutions of the kind in this country, being probably

antedated only by the Massachusetts and New Jersey Medical Societies," and, to use a somewhat trite expression, it had its birth in the "times which tried men's souls." The colonies had, it is true, gained their independence, had adopted the constitution, and had just inaugurated George Washington, in New York, as the first President of the United States. But it was not all smooth sailing yet. We are told that the nation was confronted by grave financial embarrassment; its energies as well as its resources seemed exhausted by the prolonged struggle through which it had just passed. The people, so long accustomed to war, were now ill fitted for the pursuits of peace, and, feeling very keenly the pinch of hard times, soon began to be discontented, and rebellion threatened even the very existence of the newly organized Government.

Of the medical men whose services were so indispensable to the existence of our country in its earlier days none were more distinguished than those of Delaware. The first President of this Society, Dr. James Tilton, was a man of broad culture, and his distinguished services throughout the Revolutionary War very justly entitle him to be named as one of the trio of great men in the profession in that day, namely: Rush, Warren, and Tilton. He had the honor, as you know, to be elected to a professorship in the University of Pennsylvania, which he declined, in order to continue in his country's service, and upon the breaking out of the war of 1812-15 he was made Surgeon-General of the United States.

Dr. Joseph Philip Eugene Capelle, another one of the corporators of this Society, served upon the staff of Lafayette, and when the great general was wounded at the battle of Brandywine Dr. Capelle was the first to offer him surgical aid. Of Dr. Edward Miller, another of the patriots of the Revolution, and one of the charter members of this Society, its first Secretary, and the first to deliver the annual oration before it, the great Rush declared that "he was second to no physician in all this country."

It does not come within my scope to give an historical sketch of the members of our Society, the historian of the day has already attended to this part of the programme; but I have cited a few examples only from his statements, to show you that "our ancient record is an honorable one." "There were giants in those days," men who were further in advance of the times in which they lived than any we now number in our membership.

For one hundred years the meetings of the Medical Society have been the Mecca to which the faithful have journeyed once a year. Yes, journeyed is the term, for it must have taken at least three days for a man from Wilmington or Sussex to attend a meeting here in Dover—one to come, one to attend the meeting, and one to return home again. But to-day we step aboard of a fast train, have agreeable companions, and after spending an hour or so pleasantly chattering and, as the train proceeds, constantly deriving new pleasures by being joined at every station by old friends whom we have not seen since our last meeting, we reach our destination and find ourselves all together, Sussex, Kent, and New Castle. I will not

attempt to describe what follows. It is a grand old reunion, and yet I doubt that so large a percentage of the medical fraternity attend its meetings to-day as there did in those good old days.

#### EFFECTS OF CORROSIVE SUBLIMATE.

The following symptoms have been observed in cases of poisoning caused by vaginal or intra-uterine injection with corrosive sublimate:

*The alimentary canal.* Thirst, foul breath, metallic taste, red or bluish color and swelling of the gums; redness, ulceration and sloughing of different parts of the mucous membrane of the buccal cavity; deep ulcers in the tonsils; soreness and looseness of the teeth, and sometimes salivation; vomiting, abdominal pain, tenesmus; profuse stinking, often bloody, diarrhoea. The feces contain mercury. It has been found in numerous cases after vaginal or intra-uterine injections of a solution of 1:3000, followed by the injection of plain water. Even when the solution was so weak as 1:4000, it was found in one case, but in the others not. In the majority of cases it is found the next day, and it is yet found a long time after discontinuing the use of the bichloride.

*The uropoietic system.* There is a marked diminution in the amount of urine, rising to absolute suppression of the secretion. The urine is dark, grumous, contains much albumin, mercury epithelial cells from the kidneys and hyaline or granular casts.

*The skin* is often wet with perspiration; it has been found hyperæsthetic, itching, pale or erythematous. Sometimes there is considerable swelling of the subcutaneous tissue.

*The nervous system.* In the beginning the patient is restless, and suffers from insomnia; later she becomes drowsy, sometimes delirious; and finally she collapses. In some cases spasmodic twitchings or cataleptic stiffness has been found in the extremities. The pupils are sometimes contracted as in opium poisoning. Sometimes there is a sensation of being choked.

*The pulse* is rapid and weak, the temperature subnormal.

Of these symptoms the most characteristic are the diarrhoea, the diminution or suppression of the urinary secretion, the stomatitis, the low temperature, and the presence of mercury in the urine and the stools, which may be found by chemical analysis.

The chief changes found after death are hæmorrhagic infiltration and extensive ulceration, sometimes diphtheritic patches and sloughs of the large intestine. In some cases a lower degree of inflammation is found in the ilium. Exceptionally, the œsophagus has been found inflamed. In some cases there has been found local peritonitis.

In the mouth and throat are found the above-mentioned changes.

Another constant change is parenchymatous nephritis. Sometimes deposits of phosphate of lime are found in the convoluted or straight tubules, but these calcareous deposits are often absent, and may, on the other hand, be found under different circumstances.

In some cases the substance of the brain was found dry; in other there were extravasations of blood in the meninges.—GARRIGUES, *American Journal of the Medical Sciences*.

## SOCIETY PROCEEDINGS.

## American Ophthalmological Society.

*Twenty-Fifth Annual Meeting, held at Pequot House, New London, Conn., July 17 and 18, 1889.*

*(Concluded from page 210.)*

DR. EMIL GRUENING, of New York, read a paper on

## THE USE OF THE CURETTE IN ANTERIOR TRACHOMA.

The speaker often referring to the various measures proposed for the relief of this condition, described an operation which he had employed in eleven eyes during the past ten years. A 6 per cent. solution of cocaine was first instilled. The surface of the cornea and the vessels present were then scraped away with a gouge-shaped instrument, and the vessels followed well on to the conjunction. The eye is then washed with boric acid solution, and warm compresses applied for four or five days. In three cases new vessels formed, and the operation was repeated. The ultimate result in all the cases was highly satisfactory. In old and protracted pannus, this operation may be recommended for its directness, simplicity and efficacy.

DR. S. D. ST. JOHN, of Hartford: I have used this operation in one case with the highly gratifying result of increasing the vision from  $\frac{1}{200}$  to  $\frac{1}{60}$ . This has since still further improved.

DR. H. F. HANSELL, of Philadelphia, read a paper on

## CORNEAL ABSCESS.

Describing its symptoms and referring to the differential diagnosis between it and ulcer. He protested against the use of cocaine in abscess or other inflammatory conditions of the cornea. A few drops of a strong solution will often destroy the epithelium. Instillation of eserine alternating atropine was recommended. Operative interference should be limited to evacuation of the pus.

DR. CHARLES J. KIPP, of Newark, read a paper entitled

## FURTHER OPERATIONS ON MALARIAL KERATITIS.

The author had called attention to this condition in a paper read before the Society in 1880. He had seen 120 cases of the disease. In all there had been paroxysms of malarial fever, and in 90 per cent. the corneal inflammation followed a few days after a paroxysm. In 25 per cent. the patients had suffered from similar trouble in previous attacks of malaria. The inflammation of the cornea occurred in the form of resipiginous ulceration, with narrow prolongations. The

trouble began as a line of small grayish elevations, which soon broke down, forming a furrow of ulceration. In mild cases the duration is two or three weeks, while in severe cases it may last several months. There is a marked tendency to recurrence in subsequent attacks of malarial fever. In a few cases he had seen a similar affection in non-malarial individuals. The treatment consists in remedies directed to the general condition and in mild cases with warm fermentation. In severe cases a 1 per cent. or a 2 per cent. solution of nitrate of silver applied directly to the furrow after the use of cocaine answers well. In some very severe cases the actual cautery was employed. This arrested the progress of the disease and stopped the pain, provided the malarial trouble had previously been cured.

DR. HENRY D. NOYES, of New York: During the past fifteen or 20 years, I have met with cases of superficial keratitis due to malaria. It is rare to find the deeper tissues invaded. I am led to suspect a malarial origin in cases where there is exaggerated tenderness of the supra-orbital nerve and distinct anæsthesia of the surface of the cornea. The form of ulcerative keratitis which has been described I regard as of mycotic origin, and have cured it by scraping thoroughly the lines of infiltration.

DR. T. Y. SUTPHEN, of Newark: I have seen cases similar to those described by Dr. Kipp, in patients suffering with malaria, and where there has been no distinct chill, the individuals have resided in malarious districts.

DR. JOHN GREEN, of St. Louis: I have seen many cases in which malarial fever was followed by superficial keratitis, or keratitis modified by neglect or improper treatment. I have not met with the form described by Dr. Kipp.

DR. EMIL GRUENING, of New York: I have seen this form of ulcerative keratitis, but I have associated it with the teeth. These patients have had tartar on the teeth, and have been in the habit of moistening the lids with saliva. I think therefore that the source of infection is in the mouth.

DR. SAMUEL THEOBALD, of Baltimore: I have also seen for many years this keratitis associated with malarial trouble. These cases do not always show ulceration of the cornea. I have in a general way regarded this condition as analogous to herpes zoster. I have once or twice seen iritis associated with the keratitis following malaria. In one case of malaria I have seen this keratitis with herpes zoster of the temple.

DR. J. A. LIPPINCOTT, of Pittsburgh, read a paper on

## IRRIGATION OF THE ANTERIOR CHAMBER.

This procedure is useful for the removal of débris in cataract extraction and of clotted or liquid

blood. In order to accomplish this successfully it is necessary to have an apparatus which can be readily made and kept aseptic; which will always be ready for use; which can be easily handled and the movement controlled with one hand; whose ejecting force is capable of being easily regulated; and which is free from liability of forcing air bubbles into the anterior chamber. As fulfilling these requirements he exhibited an apparatus consisting of a small metal receptacle with which was connected a rubber tube ending in a metal nozzle; the flow of liquid being controlled by a short piston in a rubber handle through which the rubber tube passed. The ejecting force can be varied by elevating or lowering the receptacle.

DR. E. GRUENING, of New York, exhibited a small flask devised by von Graefe for the same purpose.

DR. DAVID WEBSTER, of New York, exhibited two specimens of sword fishes' eyes.

DR. HENRY D. NOYES, of New York, exhibited a spectacle frame in which the nose-piece of the eye glass was combined with the ordinary spectacle frame.

DR. HENRY D. NOYES, of New York, read a paper on

#### ENUCLEATION OF THE EYE IN PANOPHTHALMITIS.

There have been reported by observers thirty or forty deaths following enucleation, almost all from meningitis. About one-half of the fatal cases have occurred after enucleation during acute suppurative panophthalmitis. At the New York Eye and Ear Infirmary there have been no deaths from this cause when no additional operations in the orbit, such as the removal of tumors, etc., have been done. The number of enucleations from 1868 to 1888 was 1,164; the number of eviscerations seventeen. Panophthalmitis existed in 14 per cent. of the cases. It seems fair to conclude that whilst a small risk to life is incurred by enucleation of the eye, the supposed increased risk by the existence of suppurative panophthalmitis is not so far justified by the facts as to bar its performance in this condition.

#### AFTERNOON SESSION.

DR. H. KNAPP, of New York, read a paper on  
THE TREATMENT OF CARIES AND NECROSIS OF  
THE ORBIT.

The upper wall of the orbit is the most frequent seat of disease and here its consequences are most dangerous. In every case of caries and necrosis of the orbit the condition of the neighboring cavities, and especially the nose, should be carefully investigated. Foci of suppuration should be freely opened, the cavity thoroughly cleansed and drainage established. This can be well accomplished by small silver tubes provided with flanges. Rough bone should be scraped away with a sharp spoon. Necrosed portions of bone should

be removed as soon as they become loose or when they can be detached without injury to adjacent tissues. The eyeball should be protected, and if there is insufficient closure of the lids, a plastic operation should not be postponed until the cornea becomes ulcerated from exposure.

DR. H. W. WILLIAMS, of Boston, read a paper on

#### MULTIPLE CYSTS OF THE IRIS OCCURRING IN BOTH EYES.

The subject was a girl 9 years of age. In the right eye there was a projection resembling a large cyst extending from the upper margin of the pupil. A similar growth projected from the temporal border. At the inner margin there were two small pedunculated growths. All were of the color of the iris. In the left eye, two somewhat oval cysts filled the pupillary space. Through the square opening left in each pupil there was a little oblique vision.

DR. T. Y. SUTPHEN, of Newark, read a paper on

#### SARCOMA OF THE OPTIC NERVE.

The patient was 10 years of age. The tumor involved the left orbit and was of two years' duration. It was mushroom-shaped and sprang from the optic nerve. Its size was  $6 \times 5\frac{1}{4}$  inches, and 2 inches thick. It was readily removed with curved scissors. As much as possible of the nerve was removed.

DR. GEORGE C. HARLAN, of Philadelphia, read a paper on

#### EXTENSIVE VASCULAR GROWTH IN THE VITREOUS.

The patient, a woman *æt.* 50, presented herself November 29, 1888, on account of disturbance of vision. Examination of the right eye showed the fundus to be slightly hazy, with small, dull white spots about the macula, the remains of old hæmorrhages, but no recent exudation. The disc was obscured by a delicate network of vessels. Otherwise there was no opacity. There was no stroma. Up to March 2, 1889, there had been several retinal hæmorrhages, but there had been no change in the vascular membrane. Vision had been reduced to  $\frac{2}{20}$ .

DR. O. F. WADSWORTH, of Boston, described two cases of

#### EXTRACTION FROM THE VITREOUS OF PIECES OF STEEL BY THE MAGNET.

in which the piece of steel was removed by passing an electro-magnet into the vitreous through an opening in the sclera. In the second case, the operation was followed some weeks later by a separation of the retina beginning at a point opposite that at which the puncture was made.

DR. J. O. TOMLEY, of New York, read a paper on

#### CORNEAL TRANSPLANTATION.

The speaker reported a case in which he had done this operation for opacity of the cornea. At

the first operation the opacity was not removed to its full depth, and although the cornea cleared to a certain extent the result was not satisfactory. The operation was therefore repeated, but without any improvement in vision. In both operations there was primary union of the graft and in neither was there any inflammatory reaction.

DR. L. WEBSTER FOX, of Philadelphia: I have performed the same operation in a case of opacity of the cornea where the patient could just distinguish light from darkness. The graft healed readily without inflammatory reaction, and the patient obtained useful vision and could almost count fingers.

DR. CHAS. A. OLIVER, of Philadelphia, read a paper entitled

AN ANALYSIS OF SOME OF THE OCULAR SYMPTOMS  
OBSERVED IN SO-CALLED GENERAL PARESIS.

These operations were made on twenty well-marked cases of general paralysis of the insane. The study was limited to subjects in the so-called second stage of the disease, where the psychical symptoms had become of such a character as to necessitate control and where motor and sensory derangement had become more or less manifest. Care was taken that each subject was seemingly free from any extraneous general disease or local disorder, and the entire study was limited to the male sex, so as to escape any conflicting or complicating changes that might appear in connection with the many diseases peculiar to the female sex. Thirty observations were made, resulting in the following summary:

1. The sensory changes herein described, which have been limited to unequal optic nerve degeneration, decrease of retinal circulation, with sub-normal direct and excentric vision for both form and color, distinctly show lowered sensory response.

2. The motor symptoms, consisting in unequal and feeble movements of the irides, causing inequality and irregularity of pupillary areas, the peculiar form of ataxic nystagmus, the slight loss of ciliary tone, all express want of proper muscle action—true paresis.

3. The peculiarly local conditions shown in the fundus, such as the pigment massings, the crescents of absorption, the disturbed and granular condition of the choroid, etc., all indicate wear and tear of an abused and irritated organ.

4. Therefore these observations upon the ocular apparatus, which were most probably made during the second stage of the disease known as general paralysis of the insane, show not only local changes, but distinctly demonstrate that the series of sensory motor disturbances found, are but the peripheral expressions of one of the many indices of gradual loss of neural strength and power in this disease.

DR. GEORGE C. HARLAN, of Philadelphia, re-

ported *A Case of Hysterical Blindness* of ten years' duration in a male 22 years of age.

DR. SAMUEL B. ST. JOHN, Hartford, described *A Case of Hemianopsia* with peculiar cerebral symptoms.

DR. B. ALEX. RANDALL read a paper on *Simple Tests of the Ocular Muscle*.

DR. T. Y. SUTPHEN, of Newark, N. J., reported

A CASE OF DOUBLE PURULENT CHOROIDITIS RESULTING FROM MENINGITIS.

February 23, 1887, was called in consultation to see G. W. B., a robust farmer, æt. 39 years. He had always been healthy with the exception of an occasional "bilious headache." Never had had any specific trouble. The history was that on February 9 he came in at noon perspiring very freely. That evening he suffered with intense headache. The next morning he was apparently well, but at breakfast had a violent chill with aching of the whole body. This was followed by high fever. Leaving the breakfast table was the last that the man remembered for three months. From this time the patient rolled and tossed in bed without decided delirium, but being in a stupid condition and easily restrained. Questions were answered only after frequent repetition and the replies ran off into complete incoherence. On the third day of the illness the body became quite rigid with the head thrown backwards. On the fourth day, the left hand and forearm became swollen and the right eye inflamed. The left eye became inflamed on the tenth day. Later the left foot became swollen. The swelling of the hand and foot lasted about a week and then subsided. The fever then became less violent and the general condition improved, but the mental sluggishness remained. There was no paralysis, no convulsion, no vomiting. At the end of the third week he had a slight chill, and another after he was out of bed.

At present the man is apparently in good health. He has lost none of his functions and the mind is perfectly clear. When first seen by the writer the eyes were in the following condition: No swelling of the lids; moderate pericorneal injection; cornea clear; anterior chamber normal in depth; irides slightly discolored. Pupils moderately dilated, with a yellowish reflex from the anterior portion of the vitreous. There was no perception of light. No tenderness on pressure, but a marked lowering of the tension of the globe. Three days later, the anterior chamber in each eye was obliterated by pressure from behind the lens, the eye-balls being harder than normal. One week later, the anterior chamber was again restored and tension had again fallen much below the normal. From that time there was progressive atrophy of both eyes until now there is left only the greatly shrunken globes, with, of course, absolute blindness.

In this case there must have been an extension of the intracranial inflammation along the sheath of the nerves and not a forcing of the products of inflammation forwards, as sufficient pressure within the cranium to produce this must evidently have become apparent by more or less paralysis.

The case is reported simply as a clinical contribution to this somewhat rare and obscure trouble, which is certain to be met with in the course of practice.

#### THURSDAY, SECOND DAY.

DR. O. F. WADSWORTH, of Boston, reported a case of *Torticollis Cured by Tenotomy of the External Rectus*.

DR. MYLES STANDISH, of Boston, read a paper on

#### PARTIAL TENOTOMIES IN CASES OF NEURASTHENIA WITH INSUFFICIENCY OF THE OCULAR MUSCLES.

The author reported five cases in which he had performed this operation on account of constant headache, inability to use the eyes and neurasthenic symptoms. In all but one there was marked and prompt relief of the local and general symptoms by the operation. Cases requiring operation are comparatively rare.

DR. DAVID COGGIN, of Salem, read a paper entitled

#### NOTES ON SOME VAGARIES OF ACCOMMODATION.

A case was of hypermetropic astigmatism passing into myopia. A case of recurrent spasm of accommodation was also reported. The third case was one of temporary anomaly of sight occurring daily. In the morning could see well, but in the afternoon could not distinguish objects across the street. Double vision also occurred. The disturbance is gradually disappearing.

DR. E. E. HOLT, of Portland, read a paper on the

#### EFFECT UPON THE ACCOMMODATION OF A PATIENT'S EYE CAUSED BY LOOKING INTO THE MIRROR SET OBLIQUELY IN THE ROOM DURING OPHTHALMOSCOPIC EXAMINATION.

Directing the patient to look with one eye into a mirror set obliquely while the other was examined with the ophthalmoscope, an element of ease was found in making the examination, and of comfort and steadiness on the part of the patient never experienced before. The eye fatigues quickly in looking at a single object. Looking into the oblique mirror gives the impression of gazing into the distance. A notable change in the pupil will be observed when the patient is directed to look at an object at the distance of the mirror, and when he is directed to look at objects reflected from it.

DR. O. F. WADSWORTH, of Boston, read a paper on

#### PARALYSIS OF THE SPHINCTER IRIDES.

A case was reported of paralysis of the sphincter irides, without affection of the accommodation lasting several months, and following the instillation of homatropine in both eyes.

DR. SAMUEL THEOBALD, of Baltimore: In all such cases it is important to exclude malingering. It would be possible for the patient by the use of a weak solution, to keep up the mydriasis without affecting the accommodation.

DR. SAMUEL D. RISLEY, of Philadelphia: Another protracted explanation of such cases is the use of pipette previously used for a solution of a mydriatic, for a solution which contains no mydriatic.

DR. JOHN GREEN, of St. Louis, presented a series of *Geometrical Constructions, illustrating certain cases of oblique pencils refracted at cylindrical and spherical surfaces*.

DR. JOHN GREEN also read a paper on *Some of the Stereoscopic Alterations Evoked by Unequal Glasses placed before the two Eyes*.

DR. SAMUEL THEOBALD, of Baltimore, read a paper on

#### THE EMPLOYMENT OF OLEATE OF VERATRIA TO FACILITATE THE DETERMINATION OF ERRORS OF REFRACTION.

A mydriatic affords valuable aid in myopia and in hypermetropia, but in astigmatism its use is not so satisfactory. In astigmatism he had found great help from the use of a 10 per cent. oleate of veratria to the temple and forehead once a day for three or four days. This seems to exert a quieting effect upon the ciliary muscle, and especially of the radiating fibres and lessens the tendency to a symmetrical accommodation. The following rule was formulated in regard to the correction of astigmatism: When the astigmatism is according to the rule, we need correct only that which is readily made manifest. On the other hand in astigmatism against the rule, we are warranted in arresting fully every part of the defect which can be rendered manifest.

DR. E. E. HOLT, of Portland, read a paper on

#### THE INEFFICIENCY OF HYDROBROMATE OF HOMATROPINE IN CONTROLLING THE ACCOMMODATION FOR THE PURPOSE OF FITTING GLASSES.

The experience of the writer was that this drug could not be relied upon. He reported one case in which the lateral hypermetropia revealed by 3 per cent. solution of hydrobromate of homatropine, was just one-half of that revealed by 1 per cent. solution of atropia.

DR. EDWARD JACKSON, of Philadelphia: I have found homatropine entirely satisfactory

when used properly. The instillations must be repeated at short intervals five or ten minutes, and three or four instillations practiced. The effect rapidly passes off, and the examination must be made within one or two hours. I have followed the use of homatropine by another mydriatic without alteration in the result.

DR. EDWARD JACKSON, of Philadelphia, read a paper on

#### AMETROPIA AS DETERMINED UNDER COMPLETE MYDRIASIS.

He had examined 4,000 eyes under complete paralysis, and presented the following table of his results. These were compared with results obtained by another observer :

	With Mydriasis.	Without Mydriasis.
Compound hyperopic astigmatism. . . . .	40 <sup>6</sup> / <sub>0</sub>	9 <sup>12</sup> / <sub>0</sub>
"    myopic    "    "    "    "    "    "	9 <sup>0</sup> / <sub>0</sub>	11 <sup>0</sup> / <sub>0</sub>
Simple hyperopic    "    "    "    "    "	6 <sup>0</sup> / <sub>0</sub>	16 <sup>12</sup> / <sub>0</sub>
Simple myopic    "    "    "    "    "	2 <sup>0</sup> / <sub>0</sub>	24 <sup>0</sup> / <sub>0</sub>
Mixed astigmatism . . . . .	6 <sup>12</sup> / <sub>0</sub>	2 <sup>0</sup> / <sub>0</sub>
Hyperopia . . . . .	31 <sup>0</sup> / <sub>0</sub>	10 <sup>0</sup> / <sub>0</sub>
Myopia . . . . .	4 <sup>0</sup> / <sub>0</sub>	9 <sup>12</sup> / <sub>0</sub>
Emmetropia . . . . .	1 <sup>12</sup> / <sub>0</sub>	17 <sup>12</sup> / <sub>0</sub>

DR. JACKSON also presented a paper on *Accuracy in the Prescription of Prisms*.

DR. W. S. DENNETT, of New York, read a paper in which he suggested a *New Unit of Angular Measurement for Prismatic Glasses*.

DR. GEORGE C. HARLAN, of Philadelphia, exhibited *Periscopic Cylindrical and Sphero-Cylindrical Lenses*.

DR. W. F. MULTENDORF, of New York, reported

#### A CASE OF AMBLYOPIA DUE TO CHLORAL HYDRATES.

The object was to put on record a case of toxic amblyopia, due to chloral hydrate. The patient had for six months been in the habit of taking 40-60 grains of the drug at night to induce sleep. Suspension of the drug relieved the amblyopia.

#### EXECUTIVE SESSION.

Officers for ensuing year: President, Dr. Hasket Derby, Boston; Vice-President, Dr. George C. Harlan, Philadelphia; Secretary and Treasurer, Dr. Samuel B. St. John, Hartford; Corresponding Secretary, Dr. J. S. Prout, Brooklyn; Delegate to the Executive Committee of the Congress of American Physicians and Surgeons, Dr. John Green, St. Louis; Alternate, Dr. D. B. St. John Roosa, New York.

The following were elected to membership: Dr. Carl Koller, New York; R. A. Reeve, Toronto, Canada; Dr. David Harrower, Jr., Worcester, Massachusetts; and Dr. George E. de Schweinitz, Philadelphia.

The Society then adjourned to meet at the Hotel Katerskill, the third Wednesday of July, 1890.

#### American Otological Society.

*Twenty-second Annual Meeting, held at the Pequot House, New London, Conn., July 16, 1889.*

The Society was called to order by the President, DR. J. S. PROUT, of Brooklyn.

DR. B. ALEXANDER RANDALL, of Philadelphia, read the first paper, entitled

#### INFLAMMATION OF THE TYMPANIC ATTIC AND PERFORATION IN SHROPNEILL'S MEMBRANE.

The author reported twenty cases, fifteen of which had been seen in the past six months, and urged that the condition was not a rarity. It often coexists with one or more perforations of the other parts of the drum head. If sought and recognized early, it is a less tedious and serious matter than these attic inflammations are generally considered to be. He cited some 120 cases reported by several observers among 10,000 patients, and while he had seen a still larger proportion, accepted this as the average. Passing over the treatment as having been already thoroughly discussed, he turned to the question of causation, and cited the view of Waib that infection from without through a "foramen Ravinii" was the starting-point. Contesting this view as to any colobomatous opening in the flaccid membrane as wholly negatived by modern embryologists, he urged that the individual variations in the septa in the attic predisposed some cases to localized inflammation and led to perforation at this point; and that these cases, neglected or recurrent, formed the group from which the usual obstinate cases were derived. He therefore advocated scrupulous search in all cases for disease in this locality as promising to nip in the bud what might later become disease notoriously difficult to control. The paper was illustrated by drawings and photographs of specimens.

DR. S. O. RILEY, of Philadelphia: I have frequently seen perforations elsewhere associated with perforations in Shropnell's membrane. The presence of perforations in other parts of the drum membrane does not exclude its presence in Shropnell's membrane.

DR. J. O. TANSLEY, of New York: I have never met with perforation of the drum to which the doctor refers, associated with perforation in other parts of the drum. A singular thing is that we so rarely get the perforation whistle.

DR. S. O. RICHIE, of Washington: I do not think that perforations of Shropnell's membrane are so common as has been stated. My experience with the absence of perforation whistle corresponds with that of others. I have had cases in which perforations in other parts of the drum healed but the perforation in Shropnell's membrane persisted. In treating these cases, besides using measures through the external auditory

meatus, I have employed injections through the catheter consisting of nitrate of silver 1 part, boric acid 10 parts, glycerine 20 parts and water 500 parts.

DR. GORHAM BACON, of New York: I have not observed this condition so frequently as Dr. Randall. It is often difficult to see these perforations. In treatment I have generally used Blake's extra-tympanic syringe. By persistent syringing and the use of astringents, cicatrization is often produced. These cases are, however, very tedious.

DR. J. A. ANDREWS, of New York: In treating these cases in which there is purulent inflammation of the attic with a large hole in Shroppnell's membrane, after injecting the cavities, I wash out the fluid by means of this instrument, consisting of a delicate metal tube with a curved extremity to which is attached a rubber tube. I use simply a boric acid solution. After washing out the fluid I dry it with cotton wrapped on a probe. I then blow in a fine cloud of boric acid.

DR. HERMAN KNAPP, of New York: There is a capital difference between perforations in the upper and those in the lower part of the drum membrane. Those in the lower part may close in a few days, while in the upper part they may continue for months or years. I think this is due to difference in anatomical structure. The lower portion is a specific tissue with little association with periosteum, while the upper part is a duplication of periosteum and skin. When the latter part is affected the process extends to the periosteum, leading to caries and necrosis of the bone.

DR. F. M. WILSON, of Bridgeport, Conn., reported

#### THREE DEATHS FOLLOWING SUPPURATIVE OTITIS, WITH TWO AUTOPSIES.

Cases in which death follows a first attack are so rare that it was thought of value to report these cases. The first patient was æt. 40 years, who for two weeks before coming under observation had had pain in both ears. February 27, 1888, the pain in the left ear became very intense. March 1 he became partially unconscious and remained so, with occasional convulsive movement, until March 6, when he died. The mastoid was drilled  $\frac{1}{2}$  inch but no pus found. No autopsy was made.

The second case was a male æt. 23 years, who was attacked with subacute otitis March 11. Symptoms of meningitis appeared, with high temperature, and he died March 27. At the autopsy one-third of the base of the cerebrum was involved in the purulent process, which extended up under the frontal convolutions. There was about  $\frac{1}{2}$  oz. of turbid fluid between the dura mater and inner meninges. There was pus in the labyrinth and in the tympanic cavity.

The third case was that of a boy æt. 10 years,

who was attacked with suppurative otitis September 5 and died about ten days later. At the autopsy the meninges were found normal, but an abscess containing 2 drachms of fluid was found in the cerebellum.

Dr. Wilson also presented a *Mastoid Drill*, provided with a guard which could be set at any desired point, regulating the distance to which the drill entered. The edges of the drill are sharp, so that the opening can be enlarged horizontally to any desired extent.

DR. GORHAM BACON, of New York: It seems to me that in these cases where we do not find any collection of pus in the mastoid cells, we are justified in investigating the condition of the brain.

DR. J. O. TANSLEY, of New York: I have had several of these cases, and have without success sought for some means by which we could differentiate between those cases in which there was meningitis and those in which there was abscess. In one case, Dr. Seguin made a diagnosis of abscess based upon conjugate deviation of the eyes. Subsequent autopsy showed the correctness of this diagnosis. In another case I suspected abscess. Dr. Weir opened the mastoid but found no pus. We also exposed the cerebrum, and two days later the cerebellum, but found no pus. The patient died of suppurative meningitis.

DR. S. D. RISLEY, of Philadelphia: It seems to me that in the differential diagnosis attention to the temperature in connection with symptoms of pressure is of great importance. In meningitis the temperature from the outset will be higher than in abscess, and the symptoms of pressure come on later.

DR. J. A. ANDREWS, of New York: In the past year I have made a number of autopsies in cases of brain abscess. Brain abscess may continue for a considerable time without any very positive symptoms, but where there is meningitis or phlebitis, there is usually a sudden rise of temperature with chills.

DR. OREN D. POMEROY, of New York: In a case of brain abscess secondary to tympanic disease the only marked symptom was a sudden rise of temperature, sometimes going up in half an hour from normal to 107°. Intelligence was unaffected until the last. The man gradually improved but died suddenly. The autopsy showed a large abscess of the brain covering the petrous portion of the temporal bone.

DR. ARTHUR MATHEWSON, of Brooklyn: It is often difficult to make a diagnosis between abscess and meningitis, and in fact many are mixed cases. In meningitis the pain is more marked than in abscess. In meningitis there is more likely to be optic neuritis, while in brain abscess I have noted a peculiar dark appearance about the retinal veins.

DR. SAMUEL THEOBALD, of Baltimore: The treatment of the preliminary stages of these cases

is important. It seems to me that a great deal might be done to prevent the occurrence of the conditions referred to. I have found benefit from local applications, especially atropia and cocaine and morphia and cocaine. If the bowels were constipated I should use a calomel cathartic. If there should be symptoms of cerebral implication I should administer mercury in some form to secure its constitutional effect.

DR. E. FRIDENBERG, of New York: During the past eighteen months I have made autopsies in two patients dead from cerebral abscess. In one case suppuration had lasted a year, but there had been no symptoms until a week before death, except irritability of temper. There was some odor, but very slight discharge from the ear. A week before death the patient developed pain in the ear, slight tenderness over the mastoid, followed by fever and symptoms of brain pressure. A small abscess was found in the temporo-sphenoidal lobe. The roof of the tympanum was carious and the meninges strongly adherent. In the second case the patient had had suppuration for years. Two months before death headache occurred, which was relieved by treatment. It recurred, with fever. There was some pain on pressure over the mastoid process. The symptoms again disappeared under treatment. Three weeks later he returned with similar symptoms. The next morning vomiting occurred, and that evening he died. An abscess containing two ounces of pus was found in the temporo-sphenoidal lobe.

DR. T. V. SUTPHEN, of Newark: These cases of brain trouble almost invariably follow the arrest of the flow of pus. We should look upon these cases as instances of local trouble and should treat the middle-ear by fomentations, and perhaps by poultice to bring about free discharge of pus.

DR. R. A. REEVE, of Toronto, Can.: In one case of death following acute suppurative otitis, there was the most profuse purulent discharge that I have ever seen, and it continued from beginning to end.

DR. B. ALEXANDER RANDALL, of Philadelphia: A case of cerebral abscess occurred in my practice last year in a boy, the subject of scrofulous disease of the elbow and other joints. I found both ears discharging, with caries of the auditory meatus on both sides. On the left all the mastoid tissues were involved. Under treatment the right side rapidly improved and on the left side there was also improvement. The case was then transferred to my surgical colleague. Six weeks later the ears were still in good condition, but the patient was gradually failing from the constitutional trouble. An hour before death there was suddenly a discharge of at least two ounces of fetid pus from the ear. There was no meningitis, but a large abscess cavity was found in the sphenoidal

temporal lobe and  $1\frac{1}{2}$  inch from the tympanum and connected with it by a sinus. In cases where it is thought justifiable to perform exploratory trephining of the brain an admirable and safe point is  $1\frac{1}{4}$  inches behind, and an equal distance above, the upper posterior margin of the osseous meatus. This avoids the major blood-vessels, and it would be favorable to reach the cerebellum through it.

DR. E. E. HOLT, of Portland, Me., reported a case of

COMPLETE CLOSURE OF BOTH EXTERNAL AUDITORY CANALS BY BONE IN A PATIENT HAVING GOOD HEARING POWER, WITH A PREVIOUS HISTORY OF CHRONIC SUPPURATIVE OTITIS MEDIA.

T. M., age 18 years, was seen in April, 1889, for an affection of the eye. It was incidentally learned that he had had abscesses in both ears when 7 years old and the ears discharged more or less for six years, but stopped entirely five years since. Examination showed the canals of both ears of about half the usual length and occupied by a continuation of the skin of the meatus, with no appearance of the membrana tympani. There was complete closure of the canal by what appeared to be bone by all the tests employed.

The hearing power for the voice was good. The stop-watch was heard only when close to the ear; the tuning-fork was heard about ninety seconds, both by bone and aerial conduction. König's rod, of thirty thousand vibrations per second, was heard by both ears. He heard less distinctly when both ears were closed by pressure on each tragus. Shutting the mouth and closing the nostrils did not seem to affect the hearing power much, if at all. Cases of closure of one meatus with the skin of the canal continuous over the obstruction have been observed, but the hearing power is very defective. Cases in which there is a small opening between the exostosis and the walls of the meatus are not uncommon.

DR. SAMUEL THEOBALD, of Baltimore: Four or five years ago I reported a case very similar to the one described. The newly-formed membrane was, however, nearer the orifice. The hearing power was good.

DR. B. ALEXANDER RANDALL, of Philadelphia: I have had one case in which one ear was obstructed by a bony mass. There was no evidence of exostosis. The hearing was, however, defective.

DR. E. E. HOLT, of Portland, Me., reported a case of

OTITIS MEDIA CATARRHIAL ACUTA

accompanied with facial paralysis and impairment of accommodation of the eye of the affected side. Judging from statistics one would be led to believe that paralysis of the facial nerve in connection

with the acute catarrhal inflammation of the middle-ear was not a common complication. In many cases the pain having been slight and having passed off and the paralysis having come on the patient's attention is directed to this and he seeks advice for the latter affection and the cause of the paralysis is recorded "a cold," or "rheumatic."

F., aged 24, seen May 19, 1889. Seven days before he took cold and right ear began to pain that night. This pain continued three days, when it subsided, and on the fourth day he was unable to use his lips properly. Examination showed all the characteristics of facial paralysis. Testing the eyes there was found paralysis of accommodation of the right eye. This the author knew to be a fact, because he had previously had the patient under his care and recorded the test of his eyes, and also by the fact that since the improvement of the paralysis of the face the paralysis of accommodation has disappeared.

DR. S. O. RICHEY, of Washington, D. C., read a paper on

#### THE PHYSIOLOGY OF THE INTRA-TYMPANIC MUSCLES.

The paper was the elaboration of a suggestion made by the writer in the discussion of a paper read by him at the Congress of American Physicians and Surgeons in 1888. If the membrum tympanum in purpose protects the aural tissues lying interior to it the muscles being appendages to the membrane are designed to assist the purposes of the membrane, which they do in part by protecting it from injury by the impact upon it of sound impulses violent enough to rupture an inflexible membrane firmly attached and having such a plane as to expose it to the fullest force of the concussion. The membrum tympani fulfils one of these conditions, it is firmly attached. He quoted Toynbee and Henle as having many years ago expressed somewhat similar views as to the action of the tympanic muscles, and states that he can find no reference to this subject by later writers. The shape and other peculiarities of the auditing meatus, the elasticity and capacity for motion of the drum membrane and its oblique position with relation to the meatus; the coördination between the palatal and the intra-tympanic muscles converting the tympanic cavity into an air-cushion, all indicate a similar purpose on the part of nature to guard the membrum tympani immediately and the labyrinth mediately from violence.

#### EVENING SESSION.

DR. GORHAM BACON, of New York, exhibited photographs of the ear.

#### CYSTS OF THE AURICLE.

Of late a number of cases of so-called cysts of the auricle have been reported. Not one of these, however, seem to represent a genuine cystic tu-

mor such as is found in other parts of the body. They all were situated on the anterior surface of the pinna, and were of rapid development. They either were the results of traumatism, and contained a sanguinolent fluid, or they developed without known cause. Mild inflammatory symptoms were present in all. The development within two or three weeks in almost all cases distinguishes them clearly from the slow and non-inflammatory development of true cystic tumors. All got well either by spontaneous absorption or by incision. The speaker had seen at least half a dozen of these cyst-like sub-perichondrial swellings of the auricle. He considered them to be mild cases of perichondritis, for these mild cases of circumscribed perichondritis may, instead of getting well, remain in this condition for a time and then develop into the full picture of a diffuse perichondritis. He reported such a case.

Dr. Knapp also described a case of genuine cyst of the auricle occurring in a girl 19 years of age. The growth was double the size of a large filbert, distinctly cystic, and had developed without known cause and without any inflammatory symptoms. The cyst was removed by operation, without rupture, and was exhibited. These tumors are not frequent in the auricle, but they can not be so rare as we might infer from otological literature.

DR. WM. H. CARMALT, of New Haven, presented a case of

#### EPITHELIOMA OF THE MIDDLE EAR.

The patient, a robust man aged 47 years, was first seen in June, 1888. On account of a suppurating ear (left) which had existed 42 years and had followed measles. The ear had given him no inconvenience with the exception of the discharge until a few weeks before he came under observation. He then began to have pain in and around the ear, and the discharge was exceedingly offensive. The canal was blocked by a ragged but firm excrescence, very sensitive to touch. There was slight tenderness, but no swelling or pitting over the mastoid. The pain radiated through the side of the head and interfered with sleeping. At the second visit the left side of the face was completely paralyzed. The case was regarded as one of epithelioma of the skin of the canal. The patient was seen by another gentleman, who thought the trouble might be a carious antrum. An attempt was therefore made to open the antrum, but the bone around it was so sclerosed that the cavity was practically obliterated. There was nothing of the nature of an abscess in the mastoid. The incision was then prolonged through the soft parts and into the external auditory canals. What polypoid could be reached were removed and a drainage tube inserted. The mass removed proved to be carcinomatous. In the course of a few weeks the ear

again became blocked up and the skin became involved. With the object of alleviating some of the distressing accompaniments of the condition, another attempt was made to clear it out. By chiseling away the bone posteriorly, free access to the ear cavity was obtained and the bone scraped apparently clean. No auditory apparatus was seen, simply a mass of carcinomatous tissue. The cavity was washed with a solution of resorcin and for a time the wound did well, but subsequently the disease reappeared. The discharges became again offensive and the patient exhausted, and he finally bled to death without the condition being detected, probably from erosion of the lateral sinus. No autopsy was permitted.

DR. B. ALEX. RANDALL exhibited a series of *Photographs*, and made some remarks on the use of photographs and of the lantern in teaching otology.

Dr. Randall also reported five cases of *Supernumerary Auricle*, four of the right ear, one of the left ear.

DR. T. Y. SUTPHEN, of Newark, exhibited a *Mummified Pea* which he had removed from the auditory canal, where it had lain for 19 years. The patient had been deaf in that ear since childhood. He heard the watch at one inch. After removal of the foreign body the hearing was almost normal.

DR. B. ALEX. RANDALL made some remarks upon the anatomy of the drum membrane.

DR. HUNTINGTON RICHARDS, of New York, read a paper entitled

#### TWO NOTEWORTHY CASES OF TRAUMATIC RUPTURE OF THE MEMBRANE TYMPANI.

*Case 1.*—Seen May 7. A woman æt. 30, two days before had received a box on the left ear. The symptoms were vertigo tinnitus and marked deafness. There had been no bleeding or other discharge. There were some evidences of pre-existing tympanic catarrh, in that it was somewhat depressed and moderately atrophic. Save for pronounced congestion of the manubrial vessels and a narrow red line along the border of the opening, it was not congested. The exposed inner wall of the tympanum was likewise pallid, secreting only sufficient mucus to give its surface a glistening appearance. The patient was directed to let the ear alone and a small, loose cotton obturator was placed in the auditory meatus.

*Case 2.*—A woman, æt. 23. Came under observation May 22. There was no discharge or bleeding. There was no congestion of the membrane or of the tympanic wall. The patient had complained of aural symptoms for several weeks. On May 21st she consulted a physician, who introduced a cotton-covered probe. This made her so dizzy that she had to lie down immediately and within two hours she discovered that she was very deaf.

The treatment was negative, and up to May 31st no change had occurred. The edges of the opening were then stimulated with nitrate of silver solution and a small quantity of boric acid was insufflated. Examination made a few days later showed that the opening had healed, with the exception of a small part. The patient then passed from observation.

#### EXECUTIVE SESSION.

Officers for ensuing year:

President, Dr. Oren D. Pomeroy, New York.

Vice-President, Dr. Gorham Bacon, New York.

Secretary and Treasurer, Dr. J. J. B. Vermyne, New Bedford, Mass.

Members of Executive Committee of Congress of American Physicians and Surgeons, Dr. W. H. Carmalt, New Haven; Alternate, Dr. F. B. Loring, Washington, D. C.

Committee on Membership, Drs. Arthur Mathewson, Samuel Theobald and S. D. Risley. Committee on Publication, Drs. J. J. B. Vermyne, C. J. Blake and J. Orne Green.

A committee consisting of Drs. S. C. Ayres and Wm. W. Seeley was appointed to prepare a minute on the death of Honorary Member Dr. E. Williams, of Cincinnati.

The following were elected to membership: Drs. Harlan P. Allen, Columbus, O.; Ralph W. Seiss, Philadelphia, Pa.; David Harrower, Jr., Worcester, Mass.; Robert Barclay, St. Louis, Mo.; Neil P. Hepburn, New York, N. Y.

#### BOOK REVIEWS.

A TREATISE ON SURGERY; ITS PRINCIPLES AND PRACTICE. By T. HOLMES, M.A., Cantab, Consulting Surgeon to St. George's Hospital, etc. With 428 illustrations. Fifth Edition. Edited by T. PICKERING PICK, Surgeon at St. George's Hospital, etc. Philadelphia: Lea Bros. & Co. 1889. Chicago: A. C. McClurg & Co. Pp. xxiii-1008. Price \$7.00.

The fifth edition of this well-known work, although bearing evidence of considerable emendation, represents about the same purposes as did the earlier editions: it aims to occupy an honorable place among the text-books in use in the schools, and is intended to be in a sense an introduction to Holmes' System of Surgery. The general arrangement of the work has not been disturbed, except as regards the chapter on Diseases of the Eye, which has been omitted as requiring too much of the limited space of the entire treatise were it emended so as to fairly represent the present status of ophthalmic surgery. In other respects the editor has endeavored to bring the work up to the standard of our present knowledge of

surgery without altering the general character of the work.

Among the subjects which have received the most attention in this revision, are inflammation, wounds, tumors, diseases of the bones and joints, abdominal surgery and intestinal obstruction, diseases of the breast, and operative treatment in reference to cerebral localization. It has evidently been the aim of the editor to maintain the conservatism of the older work by introducing little of anything too recent to have become in a measure classical, but one would think that a little more might have been said of recent advances made in England and in this country in the direction of the surgery of the brain, intestines, thorax, joints, etc., but little reference being made to the important advancement in these departments during the last three years: nor does it seem necessary to have retained such antiquated and ambiguous expressions as "scrofula," where tuberculosis is meant, and "caries," where definite diseases are under consideration.

The work, notwithstanding minor shortcomings, is one of the very best of that class which aims at being comprehensive in scope and concise in detail.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. \$10 00 a year. Single copies, \$1.00. Vol. 2, No. 3, June, 1889, and Vol. 3, No. 1, July, 1889. New York: William Wood & Co., publishers.

The June number of this series is a volume of 350 pages, entirely devoted to "General Orthopedics, including Surgical Operations," by Dr. August Schreiber, Surgeon-in-Chief of the Augsburg Hospital. This is a work of great interest and is rendered particularly valuable by reason of the large number of its illustrations descriptive of deformities and deformity apparatus. The bibliographical references are extremely numerous, and much attention has evidently been given by the author to the recent works of American and English writers. The following chapter headings will serve to give an idea of the scope of the work:

- Chap. 1. General Orthopedics. Surgical Orthopedic Operations.
- Chap. 2. Rachitis.
- Chap. 3. Torticollis.
- Chap. 4. Deformities of the Spinal Column. Deformities of the Thorax.
- Chap. 5. Orthopedic Affections of the Extremities.
- Chap. 6. Contractures of the Foot.
- Chap. 7. Deformities of the Toes.
- Chap. 8. Paralytic Deformities.
- Chap. 9. Orthopedic Affections following Fractures and Luxations.
- Chap. 10. Congenital Luxations.

The July number contains the following monographs and lectures:

"Cancer and Cancerous Diseases." By Sir Spencer Wells.

"Cardiac Dyspnoea and Cardiac Asthma." By Dr. S. von Basch.

"The Influence of Menstruation and of the Pathological Condition of the Uterus on Cutaneous Diseases." By Dr. L. Grellety.

"Torsion as met with in Surgical Practice; Inflammation of Bone; Cranial and Intracranial Injuries." By T. Bryant, F.R.C.S.

"Antisepsis and its Relation to Bacteriology." By D. J. Neudorfer.

Sir S. Wells finds that cancerous diseases are increasing in proportion greater than that of the increase of population, this being as true in the United States as in Great Britain. He believes, with Virchow, that so long as cancer is a local disease, it is curable. In cancer of the uterus, where the disease is limited to the parts near the os, he prevents intra-vaginal amputation by means of galvano-cautery; where the disease has extended much higher he advises total extirpation of the organ.

Prof. von Basch compares the pathology, symptoms, diagnosis, cause and treatment of cardiac dyspnoea and cardiac asthma, and gives short reports of a number of interesting cases by way of illustration.

Dr. Grellety considers briefly the relation between uterine and cutaneous pathology, together with certain considerations regarding etiology and therapeutics.

Mr. Bryant's article is the most extensive one in the volume. It is in the form of three lectures. The principal topics considered are as follows: The causes, effects and treatment of tension as met with in surgical practice; diagnosis of tension; tension from new growths; tension the result of inflammation; effects of tension as illustrated in inflammation of bone; cranial and intracranial injuries. Reports of numerous illustrative cases are included in the monograph.

Dr. Neudorfer gives a short account of the history and present status of antisepsis with its relation to bacteriology. He also gives an excellent synopsis of the chief antiseptics used before and since the antiseptic era, including the most recent members of this group of remedies.

UNDER the will of the late Dr. Alonzo Clark, a scholarship was endowed at the College of Physicians and Surgeons, New York, for the promotion of the discovery of new facts in medical science. This scholarship has an annual income of about nine hundred dollars, and the Faculty of the College have worthily bestowed it for a term of three years upon Dr. T. Mitchell Prudden.—*Medical News*, Aug. 10, 1889.

## MISCELLANY.

TENTH INTERNATIONAL MEDICAL CONGRESS AT BERLIN, 1890.—We the undersigned, do hereby give notice that, according to the resolution passed at the Washington meeting September 9, 1887, the Tenth International Medical Congress will be held in Berlin.

The Congress will be opened on the 4th and closed on the 9th day of August, 1890.

Detailed information as to the order of the proceedings will be issued after the meeting of the delegates of the German Medical Faculties and Medical Societies at Heidelberg on the 17th of September in the current year.

Meanwhile, we should feel sincerely obliged if you would kindly make this communication known among your medical circles, and add at the same time our cordial invitation to the Congress.

VON BERGMANN,  
VIRCHOW,  
WALDEYER.

Berlin N.W., Karlstrasse 19, July 8, 1889.

HEALTH IN MICHIGAN, JULY, 1889.—For the month of July, 1889, compared with the preceding month, the reports indicate that diarrhœa, cholera morbus, cholera infantum, dysentery and inflammation of the bowels increased in prevalence.

Compared with the preceding month, the temperature in the month of July, 1889, was higher, the absolute humidity was more, the relative humidity and the day and night ozone were less.

Compared with the average for the month of July in the three years, 1886-88, bronchitis increased and cholera infantum, cholera morbus and dysentery were less prevalent in July, 1889.

For the month of July, 1889, compared with the average of corresponding months in the three years 1886-'88, the temperature was lower, the absolute humidity was slightly less, the relative humidity was more, and the day ozone about the same, and the night ozone was less.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of July, 1889, at 26 places, scarlet fever at 30 places, typhoid fever at 18 places, and measles at 13 places.

Reports from all sources show diphtheria reported at 3 places more, scarlet fever at 7 places less, typhoid fever at 2 places more, measles at 6 places less, than in the preceding month.

*Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from August 3, 1889, to August 9, 1889.*

Col. Andrew K. Smith, Surgeon, is granted leave of absence for seven days, by direction of the acting Secretary of War. Par. 12, S. O. 178, A. G. O., August 3, 1889.

Major Alfred A. Woodhull, Surgeon, is granted leave of absence for two months on account of sickness, with permission to leave the Div. of the Missouri, by direction of the acting Secretary of War. Par. 5, S. O. 178, A. G. O., August 3, 1889.

Major John H. Janeway, Surgeon, is hereby granted leave of absence for two months, with permission to apply for an extension of two months. Par. 3, S. O. 52, Hdqrs. Div. of the Pacific, July 29, 1889.

By direction of the Secretary of War, Capt. John J. Cochran, Asst. Surgeon, now on duty at Ft. Adams, R. I., will report in person to the commanding General Dept. of the Platte for temporary duty with troops en route to and at the summer camp at Ft. Robinson, Neb. Upon completion of this duty will return to his proper station. Par. 10, S. O. 180, A. G. O., August 6, 1889.

Capt. Louis M. Maus, Asst. Surgeon U. S. Army (Ft. Porter, N. Y.), is hereby granted leave of absence for twenty days, on surgeon's certificate of disability. Par. 2, S. O. 173, Hdqrs. Div. of the Atlantic, August 1, 1889.

By direction of the acting Secretary of War, First Lieut. William B. Banister, Asst. Surgeon, is relieved from further duty at Ft. Wingate, N. M., and will report in person to the commanding officer, Ft. Grant, Ariz., for duty at that station, relieving Capt. Arthur H. Taylor, Asst. Surgeon, who, upon being so relieved, will proceed to Ft. Wingate, N. M., and report in person to the commanding officer thereof for duty at that post. Par. 4, S. O. 178, A. G. O., August 3, 1889.

*Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending August 3, 1889.*

Asst. Surgeon P. H. Bryant, ordered to temporary duty on ironclads, Richmond, Va.

*Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending August 3, 1889.*

Surgeon W. H. H. Hutton, when relieved at Mobile, Ala., to assume command of the Service at Baltimore, Md. July 23, 1889.

Surgeon George Purviance, when relieved at Baltimore, Md., to assume command of the Service at Philadelphia, Pa. July 24, 1889.

Surgeon J. M. Gassaway, ordered to New Orleans, La., for temporary duty. August 2, 1889.

Surgeon C. B. Goldsborough, granted leave of absence for thirty days. July 29, 1889.

Asst. Surgeon G. T. Vaughan, orders to Norfolk, Va., revoked; to proceed to Cairo, Ill., for temporary duty. August 1, 1889.

Asst. Surgeon J. F. Groenevelt, relieved from duty at Gulf Quarantine Station; ordered to Mobile, Ala., for temporary duty. August 3, 1889.

ADDRESSES.

JOHN CLARKE, PHYSICIAN, PHILANTHROPIST, PREACHER AND PATRIOT.

*An Oration delivered before the American Medical Association, June 25, 1889.*

BY HON. WM. P. SHEFFIELD,  
OF NEWPORT, R. I., LATE UNITED STATES SENATE.

No person however equipped for the duty, who duly appreciates the undertaking, can arise to address an audience of men trained in any department of science without embarrassment.

This embarrassment is increased with the consciousness of the want of the special knowledge in which the audience before me are adepts, and by the different schools of professional life in which we have been trained.

Before me is an audience of men selected from the most eminent of the devotees of the most abstruse of physical sciences, while I have no claim to their attention, but the having from an unfortunate accident, presented a case which has attracted the notice of some very eminent persons in one of the departments of their humane profession.

The teachings of experience are that the human race are prone to violate the laws of life and health, and all of the analogies of Nature as well as of the revealed law of God indicate that penalty falls upon violated law, and that there is the necessity of a curative or healing process.

Evangelical Christianity as well as civil codes, are based upon these fundamental ideas. Here rest the foundations for the necessity of the office, and from these premises may be drawn the outline of the duties of the physician. A profession sanctioned by the example of the Savior of mankind in His healing of the sick, and making the lame to walk.

The limits prescribed to me as well as the proprieties of this occasion, forbid any further advance in this direction.

I have been asked to speak to you of John Clarke. Many who hear me will ask, Who was John Clarke? I answer, the pioneer physician of Rhode Island, the first Baptist Clergyman in

America, the author and procurer of the Charter for the State of Rhode Island which remained the fundamental law of the State until May, 1843, and up to the time of its repeal was the oldest and most liberal written constitution of government in Christendom.

John Clarke was born in Bedfordshire, England, October 8, 1609. I have not ascertained where he was educated, but it has been said that he was "a master of his native tongue and learned in the ancient languages."

The Rev. D. B. Ray, on the authority of "The Trilemma," says that "he received his baptism in Elder Stillwill's Church in London." He writes, "in the year 1637 I left my native land, and in the ninth month of the same (November), I arrived in Boston." He came while the court was in session, and after the death sentence of Mrs. Hutchinson.

On the 17th of May previous, the Massachusetts General Court had enacted a law forbidding towns and persons to receive any stranger who resorted there with intent to reside in that jurisdiction, or to allow any lot or habitation to any such, or to entertain them above three weeks, but under allowance of one of the governor's council or under the hands of two of the magistrates. For a violation of this law a heavy penalty was provided.

Unhappily, Clarke entered Boston while this law was in force, and during the pendency of a bitter controversy which had arisen out of the question whether the internal evidence of the Spirit, which was called the covenant of grace, or the works demonstrated in the lives of professors, was the better evidence of justification before God.

The Rev. John Wheelwright, who was an ardent advocate of the covenant of grace, had been tried for his heresy, and was already under sentence of banishment.

And on the 20th of November, a few days after Mr. Clarke's arrival in Boston, many other persons, including Mr. Clarke, were given liberty to depart from that Colony, and Clarke went into banishment with Wheelwright, and they spent the winter in Exeter, New Hampshire. When Clarke came to Boston, he was 28 years of age. He was described as being a physician.

He complained of the coldness of the New Hampshire winter, and in Boston early in the following March, he joined eighteen of the victims of the covenant of grace, and crossed the Country to Providence, where he arrived within the first seven days of March, and from there went to Plymouth with William Coddington, to see about obtaining a place for a settlement, and then returned to Providence, and signed a compact for the settlement of Rhode Island on the 7th of March, and the next day with his co-settlers came to Rhode Island in Roger Williams' shallop, and on the 24th of March, with Coddington and Williams, went across the Bay to Canoncus's city, and there they procured the title to this island. Here they lived in caves until they could provide better shelters.

Among their early acts in the Spring of 1638, was to appoint a committee to lay out a site, and to provide for the erection of a meeting-house. Clarke was their preacher, as well as their physician. The men whom he accompanied to Rhode Island, had among them some who were gentle born, men of learning and of high characters.

They had no charter from the Crown, but had agreed upon a form of government based upon the Bible as their constitution, and the majority of the masters of families as its final interpreter only in civil things. They declared their form of government to be democratic, and for full liberty of conscience so long as conscience was not sought as a shield for breaking the public peace.

New men came among them who denied the validity of their government in the absence of a royal charter. Here a question arose which seriously threatened the peace of the Colony. Then Coddington, Clarke and others, early in 1639, removed to Newport, and there commenced the settlement of the town in which we are now assembled.

In the following December a church had been organized, and Clarke was its preacher.

John Clarke was now actively engaged with his co-settlers in establishing the Colony, and in preparing a concordance of the Bible.

In July, 1651, the church at Newport received a request from William Witter, an aged blind man of its faith and order, that some of the church would visit him at his residence in Lynn, in the Colony of Massachusetts. Clarke, accompanied by Obadiah Holmes and John Crandall, responded to Witter's invitation, and went to Lynn. On Sunday, while at Witter's, with Witter and his family and four or five other persons, while conversing upon religion, two constables arrested the three visitors and took them to the Lynn church and detained them until the next morning, when they were taken before a magistrate when, without evidence being adduced against them, they were convicted of having been taken by the constable at a private meeting at

Lynn upon the Lord's day exercising among themselves, to whom diverse of the town repaired and joined with them, for which Clarke was sentenced to pay £20 or to be whipped. He refused to pay the fine or to assent to its payment by others, yet the fine was secretly paid without his consent, while Holmes and Crandall both suffered the infliction of the alternative sentence, and were severely whipped.

A difficulty had arisen in the Colony, and in consequence thereof, William Coddington, who had been governor, had obtained from the ruling power in England, a commission to be governor of the Island of Rhode Island for life. The Colony up to that time had maintained a democratic form of government, and this change in its civil polity aroused the people to resist the change. The attention of the people was at once turned to Dr. Clarke, and a request signed by sixty-five, a majority of the freemen at Newport, and by 41, a majority of the freemen of Portsmouth, was presented to him to go to England and procure a revocation of Coddington's Commission, and to endeavor to secure a charter protecting the rights of the Colony. He accepted this service, and in November, 1651, with Roger Williams, who represented the Providence Colony, sailed for England, and here commenced Dr. Clarke's career as a Statesman. I use the term Statesman in its higher and better sense, for the popular mind overlooking literal meanings draws a wide distinction between the terms Statesman and politician. The latter thus is made to signify the art of obtaining votes by calculation, and by cunning and adroit methods, while the former implies the power to wisely organize, and prudently administer a government for the people. In this sense it will appear that John Clarke, though he was the contemporary of Sidney, of Cromwell, of Vane and of John Milton, was endowed with a genius of Statesmanship above, and in advance of that which any man of his time was enabled to practically apply to the government of a civil State.

In England Dr. Clarke was kindly received by the leaders in the great struggle which was then being carried on. Coddington's commission was at once suspended and ultimately revoked. Clarke remained in England, the agent of the Colony for twelve years, during which time he published his concordance of the Scriptures. (Aug. 3, 1655.)

In the calendar of Colonial State Papers, p. 427, is the following entry: "John Clarke, physician of Rhode Island, in America, having composed and very closely compacted a new concordance to the Holy Scriptures of Truth, which in regard of its plainness and fulness, and yet smallness of volume and price may prove singularly conducive to the help of those who desire to try all things in these trying times by that touch stone of truth. Henry Hill is licensed to print

and publish the same to the exclusion of all others, and the Company of Stationers are required to enter this order in their Register."

I am not aware that a single copy of this concordance has survived the wastes of the intervening centuries.

Clarke mortgaged his estates in Newport to Richard Dean, to obtain money in London to support himself while he was abroad on the business of the Colony.

His occupations during the twelve years he was the agent of the Colony in London, are largely left to inference and to the declaration of the town of Warwick, which in refusing to pay its proportion of the expenses, he incurred in rendering his great service to the Colony while in England said: "He was much employed about modeling of matters concerning the affairs of England, in which no doubt he was encouraged by men of no small estates." It is known that he was on intimate terms with, and was often the guest of Sir Henry Vane, and that he sustained friendly relations with other leading men in England in the time of the Commonwealth.

Both Massachusetts and Connecticut sought, while Dr. Clarke was the agent of the Rhode Island Colony, to obtain parts of the territory of the latter Colony to be annexed to their respective territory. Clarke, by unwearied exertion, and with remarkable address, defeated these designs. In 1662, in behalf of the Colony of Rhode Island, he presented two addresses to the Crown, asking for a Royal Charter. If Clarke's fame stood alone upon these wonderful State papers, he would have been regarded as having made one of the boldest and clearest conceptions of the rights of persons, and of the most advanced theories of civil government that up to that time had ever been announced. He closed the second of these Addresses with the following passage, which was embodied in the Charter:

"Your petitioners have it much on their hearts, (if they may be permitted) to hold forth a lively experiment, that a flourishing civil State may stand, yea, and be best maintained, and that among English spirits, with a full liberty in religious concerns, and that true piety rightly governed upon gospel principles will give the best and greatest security to true sovereignty, and will lay in the heart of men the strongest obligations to a true loyalty."

The Charter was granted by the King to the great displeasure of his counsellors of State, and new principles were thus embodied into civil government. Mind was emancipated when conscience was made free. And a people were enabled to make their own laws which by the charter might be pleaded in bar to an Act of Parliament or of the King. Laws which were not to be subjected to the risks of a royal veto. And under that charter, says Calmers, the people

of Rhode Island acted as if they were without the King's dominions. It is safe to say, that up to that time, and until after the American Revolution, no fundamental law of any State in Christendom had embodied absolute freedom in religious concerns, and so large a measure of civil liberty, as was embraced in the Charter of 1663.

On the 24th of November, with every possible demonstration of joy, the assembled freemen of the Colony adopted the Charter, and it became the fundamental law of the State, and so it remained until May, 1843.

The expressions of the gratitude of the Colony to Dr. Clarke and to the King, couched in language of extreme eulogy, were returned to them in England. While this charter was yet the fundamental law of the State, said Bancroft, the venerated historian of our country, "no where in the world has life, liberty, and property been better preserved than in Rhode Island under this royal Charter."

Graham, the Scotch historian, arraigned Dr. Clarke for the manner in which he obtained this Charter from the Crown. This attracted the attention of Mr. Bancroft, who was the first prominent writer of American history to do justice to the founders of Rhode Island, and he demonstrated that the charges of Graham rested mainly upon what occurred at Westminster between the King and John Greene and Randall Holden, who went to England after the decease of Dr. Clarke, not as the agents of the Colony, but in behalf of themselves and possibly some other settlers of the town of Warwick. In this controversy Mr. Edmund Quincy, and others in Boston, took the side of Graham, and Mr. Bancroft was ably supported by the late Professor Gammell. Mr. Bancroft has thus recorded his appreciation of Dr. John Clarke.

"Never did a young Commonwealth possess a more faithful friend than the modest and virtuous Clarke, the persevering and disinterested envoy, who during a twelve years' mission had sustained himself by his own exertions and a mortgage on his estate; whose whole life was a continued exercise of benevolence, and who at his death bequeathed all his possessions for the relief of the needy, and the education of the young. Others have sought office to advance their fortunes; he, like Roger Williams, parted with his little means for the public good. He had powerful enemies in Massachusetts, and left a name without a spot."

The Rev. John Callender, who was well acquainted with some of the men who in his time had known and been the associates of Dr. Clarke, said of him:

"He was a faithful and useful minister, courteous in all the relations of life, and an ornament to his profession, and to the several offices which he sustained. To no man is Rhode Island more in-

debted than to him. No character in New England is of purer fame than John Clarke."

The Rev. Isaac Backus, of Massachusetts, the historian of the New England Baptists, writing of Dr. Clarke, says :

"Mr. Clarke left as spotless a character as any man I know of, that ever acted in any public station in this country. The Massachusetts writers have been so watchful and careful to publish whatever they could find, which might seem to countenance the severities they used towards dissenters from their way, that I expected to find something of that nature against Mr. Clark, but I have happily been disappointed. Among all their authors or records that I have searched, I have not met with a single reflection cast upon him by anyone ; which I think is very extraordinary. Few men ever merited the title of a Patriot more than he did, for he was a principal procurer of Rhode Island for sufferers and exiles. And when their rights and liberties were invaded, he crossed the ocean, and exerted all his influence, in twelve years' watchful and diligent labors for his Colony at the British Court, till he obtained a new Charter for them, of great and distinguishing privileges."

At the time of the arising of the Quaker Controversy in 1658, Rhode Island had received an official letter from the United Colonies, advising it not to entertain these people, and admonishing the Colony, "if it did receive and entertain them notwithstanding the advice of the United Colonies, that these Colonies would then see what God would move them to do to save themselves and their families from the influence of Quakerism."

This occurred while Dr. Clarke was the agent of the Colony in London. And the Colony addressed a letter to Dr. Clarke upon this subject, in which its appreciation of the doctor's services is stated as follows : "We have known not only your ability and diligence, but also your love and care to be such concerning the welfare and prosperity of this Colony since you have been entrusted with the more public affairs thereof, surpassing that no small benefit which we formerly had of your presence at home, and in all straits and incumbrances are emboldened to repair to you for your continued counsel care and help, finding that your solid Christian demeanor hath gotten no small interest in the hearts of our superiors, those worthy and noble senators with whom you have had to do in our behalf, as it hath constantly appeared in your addresses made unto them, which we have by good and comfortable proofs found having plentiful experience thereof."

This letter besought Clarke "to have an eye and ear open in case our adversaries should seek to undermine us in our privileges granted unto us, and to plead our case in such sort as we may

not be compelled to exercise any civil power over men's consciences, so long as human orders in point of civility are not corrupted and violated, which our neighbors about us do frequently practice, whereof many of us have large experience, and do judge it to be no less than absolute cruelty."

Referring to the Quakers, this letter sets out : "We have found no just cause to charge them with a breach of the civil peace. They are constantly going forth amongst them about us, and vex and trouble them in point of their religion and spiritual state, and return with many foul scars in their bodies for the same."

The situation of Dr. Clarke when in England was perplexing in the extreme, for Connecticut claimed the territory of Rhode Island on the west to Narragansett Bay, and Massachusetts and Plymouth claimed the territory of the eastern part of the Colony also to the same Bay. So as the agent of the Colony he had to contend for the existence of his constituency. Happily for him, Connecticut was for a time represented in England by Governor John Winthrop, Jr., who was like Clarke a physician of eminence, and a devoted scientist. Clarke and Winthrop met as wise and just men should always meet, and agreed upon a settlement of the Connecticut boundary, the result of which settlement Clarke prudently had inserted in the Charter, and though afterwards long contentions were had between these Colonies, in which Connecticut sought to vacate this settlement, yet the boundary fixed by Clarke and Winthrop remains the line which marks the jurisdiction of the States of Rhode Island and Connecticut to this hour.

Clarke returned to Rhode Island to receive the gratitude of its people for the priceless benefaction his genius and Statesmanship had conferred upon the Colony in June, 1664.

On his return he was at once elected a member of the General Assembly, now organized under the Charter procured by his exertions, which secured beyond any lawful interference of Crown or Parliament the civil and religious liberties of the people. And upon which a government was to be framed on principles which had no traditions in the past history of the world. Clarke entered the Assembly. The first resolution to be passed was that thereafter every session of the Assembly should be opened by the reading of the patent.

A letter of thanks was drawn up and presented by the presiding officer to Dr. Clarke, and a committee was appointed to audit his accounts. He was also made a member of a committee to revise the laws of the Colony to see that they be made to conform to the Charter, and was appointed a commissioner to run the boundary line between the Colony and the Colony of Connecticut.

The distinctive principles recognized in the foundations of the government of Rhode Island in the Charter procured by Dr. Clarke were :

1. The Indians had a title to the soil of which they could not be deprived but with their consent.

2. The right of the people who owned the soil to establish a civil government for those who should reside upon it, and to determine who should be admitted to be freemen with them.

3. The freedom of conscience from the control of the State, so long as the exercise of that freedom did not tend to the disturbance of the civil peace.

4. By the Charter it was provided that the legitimate exercise of authority conferred thereby should be a bar to any prosecution therefore, against any act or proceeding of the King or of Parliament.

The credit of the discovery of these principles in government Dr. Clarke shares with others, but the incorporation of the principles of civil and religious liberty into the Charter, and the protection of Chartered rights against the invasion of King and Parliament, by anticipating and applying to this quasi-corporation the principles long after settled in the Dartmouth College case, was the work of Dr. Clarke.

To properly appreciate the merit of these provisions we should place ourselves in the situation in which Dr. Clarke was placed, and surround ourselves by the state of governmental science, as it was at the time of the return of Charles II to the throne, and the granting of this Charter, and then look forward through the intervening time, and watch the expansion of these principles in government as they, like the dawn of the coming day, have been spreading over the world. Then we reflect that principles are stronger than men; men die, but principles live forever. The principles incorporated into the Charter of Rhode Island are yet expanding and ameliorating the conditions of mankind, and will continue their work until they overthrow thrones and every where break down dynasties and hereditary privileges to govern. And the dissemination of education and morality among the masses of the people after the manner proposed by Dr. Clarke, and for which he by his will gave his private fortune, will fit the people to rise above the scrambling hoard of political pirates who now, like hungry dogs after prey, strive to obtain places which should be places of honor and trust, with as little scruple or regard to consequences as the privateersman disposes of his plunder and prize money.

Dr. Clarke was thrice married, but died childless, April 20, 1676, and was buried in what was the south-east corner of his orchard, near his dwelling, and his church on the northerly side of what is now West Broadway, in Newport.

DR. SEGUIN, of New York, has been presented to the Paris Academy of Medicine as corresponding member.

## MARKING AN ERA IN LARYNGOLOGY.

*The Address of the Chairman of the Section of Laryngology and Otology, delivered at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY WILLIAM H. DALY, M.D.,  
OF PITTSBURGH, PA.

*Gentlemen and Colleagues:*—Let us congratulate ourselves that, at last, we, as laryngologists and otologists, are in position to mark an era in the progressive history of the American Medical Association—an era of good, solid medical sense. I refer to this, the first meeting of the Section of Laryngology and Otology, as a separate and individual body disassociated from the Section of Ophthalmology, in which the two former closely related specialties have thus far in our history played a secondary rôle.

As laryngologists and otologists we have long agreed that, to be an able practitioner in either specialty, one must be a well informed and competent practitioner in both these special branches of medicine; but so far as ophthalmology is concerned, if we except certain catarrhal ophthalmias of a chronic character, there is little call for the constant special skill and daily practice of the laryngologist in the ordinary treatment of the eye. But in the interest of otology, we, as laryngologists, feel a pride that grows with experience (especially those of us who have given more than the usual attention to intra-nasal diseases), that we made no mistake in our formulated opinion expressed eight years ago, at the International Medical Congress at Copenhagen, viz.: That the laryngologist of the future must be more the rhinologist, and the rhinologist more the surgeon than the physician. For this formulated prognostic expression of opinion, the author was assailed by some excellent men and friends in our specialty, as giving a blow to laryngology; but when such able minds as Profs. Bosworth and Jarvis of New York, Roe of Rochester, Woakes of London, and others, endorsed the author's views in their daily practice, and publicly in their writings and discussions, and a host of others, such as Profs. Harrison, Allen, Sajous, etc., endorsed them by adopting them in their daily practice, it was enough that I had voiced a prediction that was being and has been entirely verified by experience.

But as to the practical application of these views, they come to us with a redoubled force and utility in by far the largest number of the inflammatory diseases of the middle ear: hence I desire to refer to them, and to this end I ask the question, "How shall we attack a chronic otitis media successfully?" How can we do it without the necessary skill of the laryngologist and rhinologist? The largest number of these cases have begun *not* in the ear, but in the naso-pharynx, and we all know are only arrested (alas! we say *arrested* advisedly) by the rational treatment.

Applied through skill in treating these intra-nasal parts, because too often the original or central disease has been neglected so long, or ignored, that the patient has suffered a permanent and irremediable damage to the middle ear, before the cause of the disability is suspected. However, no informed otologist will think of questioning the assertion that the rhinologist, and the surgical one at that, is the man who will oftenest help him out of his difficulty in all the cases of inflammations of the inner and middle ear.

Now, gentlemen, as we have for the first time in our history come together as laryngologists and otologists, the two (to us, at least) most enticing fields of medicine, where there is probably the largest possible future for good to humanity, in solid, useful and brilliant work, and hence more distinction to ourselves than even the most sanguine suspect, as you see by our programme, we have a long list of papers from able authors, about forty-eight in all, and we must strictly adhere to our rules limiting discussion; and since you have made these rules and I, as your President, simply enforce them, I trust you will aid me with the same courtesy you have always shown me, both personally and publicly, while seeking to perform the not always easy task of a presiding officer.

## AN ABSTRACT OF THE PRESIDENT'S ADDRESS.

*Delivered at the Fifty-Seventh Annual Meeting of the British Medical Association, Aug. 13, 1889.*

BY CLAUDIUS G. WHEELHOUSE, F.R.C.S.,  
CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY.

### A CURSORY REVIEW OF THE PROGRESS OF MEDICINE AND OF MEDICAL EDUCATION.

Life, as measured by the standard of the space of time allotted to each unit of the human family, is but a little span. Man has not reached his present condition of intellectual, of moral, or even of physical greatness in one generation; the white cliffs of Albion, in their formation, mark not only generations, but æons in the progress of creation. Rome was not built in a day! So medicine, as she stands to-day, strong by the acquirements of her children of many generations, did not arise upon the world in the full glory of a heaven-born science; but, sifting grain by grain of her faith from the speculations laid at her feet by her followers through countless ages, has, little by little, built up the temple of her fame until it has assumed the proportions in which we now behold it, and of which we are the accredited custodians.

#### THE MEDICINE OF THE EARLY AGES.

Sometimes in the current of events her progress has been labored and slow; with halting and uncertain steps, with Arabian mythologists, as-

trologers, and such like visionaries as her companions, she has picked her way through gloomy times of mystery, uncertainty, and doubt. At times the light of truth has shone upon her path more brightly and has cheered her on her way; and with the Harveys, the Sydenhams, the Jenners, and the Hunters, the Dupuytren, Laennec, and Pasteurs of the world for her companions she has walked with firmer steps until at last she has become an acknowledged power, and stands forth as the companion of even the exact sciences. Each generation of her votaries as it passes across the stage of the world's history, is henceforward bound to leave a mark behind it as its contribution to the sum of existence, and that mark must, in the aggregate, be the result of individual efforts.

To some it is given to do great things, and to stand revealed by the unmistakable stamp of genius. To some, by more prolonged and patient effort, to leave an impress which, if it be not so brilliant, is yet equally fruitful and enduring. And to every one of us, however humble may be the current of his life, it is permitted to make his mark, to add his little contribution to the total sum of a ceaseless progress, and to advance it or to hinder its advance.

I can look upon the broad roll of this great Association and can see there names that will never die—the names of men whose achievements will never perish, who when they sink as their predecessors have done to their rest will leave, as Harvey and Jenner left in former times, a priceless inheritance to mankind at large, whose labors will not have been in vain, and of whom the world will acknowledge that the talent entrusted to them has been productive of abundant fruit, that of a truth they have left the world better and richer than they found it.

I can see hundreds of others who are aiming at this high standard, who by their individual labors are raising the great tower of knowledge, and whose lives, though not illumined by the torch of genius, will yet leave behind them the undying results of patient labor in well-doing; and I see, in all, the roll of a great brotherhood, strong in their efforts to advance the common weal, and doubly strong in the strength of union.

To us, as medical men, all science is of transcendent interest; but, not unnaturally, the sciences which bear on life and death stand, for us, in the forefront; and to each generation as we pass across the stage of existence, it becomes imperative to seek to add something to the store of that knowledge by which life is rendered more endurable, is robbed of some of its attendant evils, some of its sorrows and some of its sufferings.

Our fathers, under disadvantages we are scarcely able to appreciate, did great things. Are we better than our fathers were?

Will you quarrel with me, if, in welcoming you to this our great annual festival, I ask you, for a few brief moments, to ponder over this important question with me?

Life, and with life the progress of science, has ever been chequered with sunshine and shadow. Evil and bright days must follow each other; good times and bad must balance one another, and if, in the great battle for existence, we incline sometimes to lay down our arms and to capitulate, we have the authority of one of the sweetest of sweet singers to revive our fainting courage:

Be still, sad heart, and cease repining,  
Behind the clouds is the Sun still shining;  
Thy fate is the common fate of all,  
Into each life some rain must fall;  
Some days must be dark and dreary;

and the lives into which, on the other hand, some bursts of sunshine of even more than usual brilliancy do not occasionally force their way are, I would fain hope, very few. . . .

The bill of fare we have provided for your enjoyment will meet, we hope, with your appreciation and approval; and if we have ventured upon the introduction of some few novelties and variations in the usual plan of the annual programme, we have done it in the sincerest hope that we may thereby advance and increase the interest of your sojourn among us.

My duty is an easy and a pleasant one. I am precluded from speaking to you on any of the directly special subjects with which we are called upon, whether as physicians or as surgeons to deal.

Medicine will be discussed, and all that can be said of it will be brought before you by one of the leading physicians of the day; and in Dr. J. Hughlings Jackson will find an exponent to whom you will join me in listening with hearty interest and attention.

Surgery, and the progress it has made and is making, will be dealt with by my friend and colleague Mr. T. Pridgin Teale, and for, I believe, the first time in the history of the Association, an address in Psychological Science will be offered you, and this we have placed in the very able hands of our former tried and ever welcome friend Sir James Crichton Browne.

Our Sections will be presided over by men, who, each in his own department, will tell us all that it is necessary for us to know to keep us abreast with its latest and highest developments, and, as individuals, you will have an opportunity, in the discussions which have been arranged for you, to bring forward any special matters with which you wish to deal, on which you may personally wish to be heard, or to impart to us any information which you have acquired or have worked out. To do this has ever been, and is still, the great object of our Association; and

who can calculate the advantage that has accrued to us, as a profession, from the accumulated labor of the fifty-seven years during which it has existed?

Union is strength, and that which men by individual labor never could have accomplished the principle of association has enabled us to do; and by yearly repeated meetings such as this upon which we are entering—with the aid of a journal by which the labors of each one may be made the common property of all—a fund of wealth which must otherwise have died with individuals has been preserved to us for ever.

Of what comparative general value were the labors of individuals in the early days of the present century in comparison with what they are now?

However brilliant the work that was done, or however intrinsically valuable, what opportunities were there of its being made known beyond the limited area of the worker himself; and how much excellent work must have been lost to the world in consequence?

#### THE COMPARATIVE ISOLATION OF PRACTITIONERS IN FORMER TIMES.

We, in comparison with preceding generations, have been possessed of advantages of incomparable magnitude. Not only in our own, but in every other science also, knowledge and the facilities for the spread of knowledge have so increased that comparison is almost impossible. Think for a moment of the changes that one generation only has seen! The facilities for personal communication that have come with the advent of railways, of steam, and, above all, of the developments of electrical science, by which not individual portions of our own kingdom only, but all the nations of the earth have been brought into inter-communication. What great discovery can now be made that does not instantly become the property of even the remotest nations of the world, and is not, by any omnipresent press, brought to the personal knowledge of every votary of science?

Does America give birth to anæsthesia? And in what part of the world does the blessing of painless surgery remain unknown? Does Sir Joseph Lister satisfy his own mind of the infinite powers of antiseptic surgery, and in how short a period of time is his brilliant discovery the common property of every surgeon in the world?

What did the surgeon of fifty years ago know of the powers of "germs," of "bacteria," of "bacilli," and of their capability to destroy his most elaborate and perfect work? And where is the student of surgery of the present day to whom they are unknown, or who is unprepared to do battle with them, one and all, and to baffle or to modify their evil influences? What the medicine and surgery of the 18th and preceding centuries

were, we are only able to conjecture. Its medicine we believe to have been little more than an empiricism founded on close observation, and led by a few master minds, and its surgery we know was crude, and, as compared with that of to-day, was even barbarous and cruel, and few of us I imagine would care to witness a major operation, as then performed, by even the most renowned and skilful surgeon.

But the light, even then, was breaking, and not many years of the present century were to run ere truer principles of both medicine and surgery were to be made known to the world, and each was, as a science, to be established on a surer foundation than any on which it had hitherto rested.

#### THE GENERAL PRACTITIONER OF THE EARLY PART OF THE PRESENT CENTURY.

Let me endeavor to draw a sketch of the average practitioner of the commencement of the present century, and there may be some, at any rate, in this room who can follow me and judge whether I paint him correctly, or whether, trusting too much to tradition and report, I do him injustice.

He was usually a hard-working industrious man, who thought little of bodily exertion, and who spent the greater part of his time in his saddle, which was his only way of getting about the country; a hard-thinking man, but one whose mental training had not been great, nor his education elaborate; whose opportunities for the acquisition of professional knowledge had been few and short; of whom it might be said that that which he knew was, in the main, either the fruit of his own observation, or of his own observation added to the traditions of the place or practice in which he had been brought up.

Knowledge and practice alike were purely empirical with him, and though he could treat disease with skill, and could, in most cases, give a good account of his warfare, it was purely by empirical means that he did it. His great panacea for all ailments was blood-letting, and his pocket was never unarmed with the all-potent lancet.

*As a Physician.*—No matter what the case might be, so long as it was "acute," venesection must precede everything else; then followed a superabundance of mixtures, powders, draughts, pills, lotions, etc., with which he hoped to effect a double purpose, first, to cure his patient, and, secondly, to remunerate himself for his attendance; for, so trifling were the charges he was able to make for his personal labor, and at so low a rate was that estimated by his patients, in comparison with the amount of medicine he gave them, that, except for the additional charges made for it, his remuneration would have been infinitesimal. He had a good sound knowledge

of drugs in general, and of what they could do; he was sadly too ready to rely on them, and his patients were compelled not only to swallow most nauseous compounds, but too swallow them also in inordinate quantities. Of the morbid anatomy of diseases he knew something, but not much; of pathology, in its true sense, he knew nothing, for physiology, whether healthy or morbid, was not one of the sciences of his day. When he "walked the hospitals" for the few months required of him, he saw a few post-mortem examinations, and had the opportunity to mark the ravages and the appearances left by various so-called diseases, and these he was apt to regard as the diseases themselves. His treatment was chiefly based on nomenclature; he could tell you what was good for "fever," what for "tic," for "rheumatism," for "indigestion," for "scurvy," and for innumerable other complaints; and he who was believed to possess the greatest number of formulæ for the greatest number of complaints was regarded as the cleverest and most desirable doctor.

*As a Surgeon.*—As a surgeon he was, as a rule, further behind the practitioner of to-day than he was as a physician. His education, such as it was, had taught him to rely, in this branch, more on the skill of others than on his own. There were certain men, well known in their several districts, as the men to whom to appeal in cases of surgical emergency, and they were the men who made world-wide reputations. . . .

#### SURGICAL OPERATIONS IN FORMER TIMES.

A surgical operation in those days was an ordeal of fearfully different magnitude to anything known to us to-day, and, naturally enough, the patient had a large say in the matter. Confidence in operations themselves and confidence in the skill of the operator were not then what they are now, and it must be remembered that when, as the only means of escape with life, an operation had to be performed, it had also to be endured in all its unalleviated agony. Courage and endurance, unfortunately are not given alike to all, and many a life which would be saved to-day was at that time voluntarily laid down, not simply for want of faith in the capability of the surgeon, but from sheer inability to face the terrible ordeal of bodily suffering involved. . . .

#### THE MEDICAL SCIENCE OF THE PRESENT DAY.

That the medical science of our time is in advance of that of the time of which I have been speaking is beyond question, and that the effects produced by increased knowledge and research have given advantages to the world of indescribable value no one will deny. Look where you will, whether over the domain of medicine or of surgery, and the facts are indisputable. The field is enlarged, the culture of the field is im-

proved, and the harvest is, beyond all question, infinitely greater, and it is surely worth our while on an occasion such as this, to ascertain, if we can, wherein lies the secret of our advance.

In a large measure it is due to our possession of vastly improved instruments of precision.

To our ancestors the revelations the microscope has made to us were but a dream. They could theorize, and argue and believe, but the things upon which they could only theorize, and argue and believe, are living verities to us. To them the existence of a *materies morbi* was only an argument, whereas now, we know not only that the causes of many diseases are indeed material, and even tangible, but that we are able to demonstrate and see them, to recognize their individuality, their specific forms, and the phenomena of their growth, propagation, and development.

I call to mind a story of two great Scotch professors—the one a theorist, the other a materialist. The materialist would argue that certain forms of disease must be due to the presence of germs, and were the direct results of their development, propagation, and multiplication; and the theorist would cry “here is your microscope, show me but one of these germs and I will believe; but, until you do, I cannot;” and, being unable to do this, his friend could only fold his hands and wait patiently, hugging his belief, meanwhile, but with the conviction of certainty none the less.

Gentlemen, picture these two professors now, if they could meet, and know only as much as we know of bacteria and bacteriology, and of the field of germ pathology. And meanwhile, yet another Scotch pathologist as fully convinced as though he could see or had seen the whole range of modern pathological development, so ponders the theory, and acts upon what he believes its possibilities to be, that, at last, he lays at the feet of his profession the whole science of antiseptic surgery. So, in like manner, and little by little, the microscope has revealed to us many of those hidden mysteries which constitute the whole science of physiology, has shown to us the beauties of capillary and lymphatic circulation, has enabled us to understand and comprehend the processes of absorption, of disintegration, and of recuperation, and has placed at our disposal the key to mysteries of which our predecessors could have but faint imaginings, but which we know, and know with a certainty which constitutes our knowledge science indeed.

Thus medicine and surgery have alike been founded on a rock of knowledge, from which they can never henceforward be dislodged, and from which in their future progress light may be made to shine, which will illumine their path along whatever roads they may advance, and will dispel many a doubt and darkness which, in former times, would have been insuperable barriers to their progress. And so, by other in-

struments of precision, barrier after barrier has been removed from our path, doubt after doubt has been cleared away, and we now see clearly where heretofore we had only seen as “in a glass darkly” and unassailable stores of knowledge have thus been placed at our disposal. What shall I say, for instance, of our advance along the pathway opened up to us by electrical science? Is not this alone one which, uncomprehended in former times, has enabled us to build up knowledge of phenomena, without which the infinite intricacies of the action of the nervous system must have remained shrouded in profound darkness, and out of the chaos of former mysteries to see, clearly defined, order and law where ignorance, hypothesis, and mystification formerly had reigned supreme. And while physiology has thus grown into a true science, pathology has also advanced with equally rapid and giant strides. We see, indeed, as our ancestors did, the ravages made and left behind in the track of disease, but we see them only as the evidences of deeper physiological mysteries; we study them as the effects of processes which have constituted the true phenomena of disease, and we seek to unravel them one by one until we see clearly how they have arisen, and what they denote. And so, with ceaseless patience, we endeavor to track down mischief to its origin and birth. Year after year our patience is rewarded by fresh discoveries, fact is added to fact, uncertainty after uncertainty is dispelled, and thus, each year, the tree of knowledge puts forth fresh shoots and brings us a more and more abundant yield of goodly fruit.

Advances, however, of such kinds as these, and in such directions, do not, in my opinion, constitute the chief or highest glory of modern medicine.

#### PUBLIC MEDICINE.

A common reproach is often brought against both medicine and its practitioners that it is a sceptical profession; that its practitioners are essentially materialists in their views; that medicine, as a science, leads to free thinking, and seeks, in a rational explanation of every fact with which it is brought into contact, to undermine our belief in things spiritual, and to lessen our faith in all that we cannot see, and handle, and account for; that constant contact with pain and suffering tends to numb our sympathy and to diminish our pity for the sufferings of mankind.

On this point I would venture fearlessly to challenge any other calling or profession to produce a parallel to the modern development of “Public Medicine,” a science which seeks ever, even at the risk of its own extinction, to exterminate the causes of disease and death, and to eradicate from the world the very springs and sources from which they arise.

“It is a Commonwealth sustained and gov-

erned by the desire existing in the minds of each of its members to do as much good as possible to every other member." It looks upon prevention as better than cure, and asserts, as is now clear to all, "that a large part of human suffering is preventable by improved social arrangements," and sets itself to the task of sweeping away all such preventable causes.

"Its compassion is all the deeper, its relief more prompt and zealous, because it does not generally, as former generations did, recognize such calamities to be part of man's inevitable destiny; and it hurries with the more painful eagerness to remedy evils which it feels ought never to have befallen."

"When the sick man has been visited, and everything done which skill and assiduity can do to cure him, modern charity goes on to consider the causes of his malady; what noxious influences besetting his life, what contempt of the laws of health, in his diet or habits, may have caused his sickness, and then to inquire whether others incur the same dangers, and may be warned in time."

"Our Great Example commanded His first followers to heal the sick and give alms, but He commands us and all His followers in this age to investigate the causes of all evils, to master the science of health, to consider the question of education with a view to health, and while all these investigations are made with free expenditure of energy and time and means, to work out the re-arrangement of human life in accordance with the results they give; and if, instead of undoing a little harm, and comforting a few unfortunates, we have the means of averting countless misfortunes, and raising by the right employment of our knowledge and power of contrivance, the general standard of happiness, we lessen the necessary evils of life, lengthen the term of human existence, wipe out the causes of innumerable griefs and sufferings, make life more endurable and happy, can it be said that we are failing to obey the commands or to undermine the teaching of our great Master?"

Can it be denied that these are among the chief aims and objects of our profession in this our day? Is not every community provided with its officer of health? Is not disease of every kind assiduously and ceaselessly tracked to its hidden birth-place? Can an epidemic now run riot as it did in former times? or devastate a whole country, as it formerly was wont to do? Look at the great scourges of the earth as described in history—at malarial fevers, at small-pox, at typhus, at cholera, at the whole host of epidemic diseases which, born of and fostered by insanitary conditions revelled in the unprotected homes of this and other countries, and sapped the health and strength of nations.

Are we not adding year by year to the vast stores of our knowledge? Are we not, by our ceaseless search after the seeds of disease, the bacilli, the micrococci, and the germs of which it comes, and by our cultivation of sanitary science, doing a mighty work in the renovation of the world and the diminution of suffering and pain? Can any work be nobler? any search after truth be more innately religious?

Thus at least I argue when I hear our profession charged with irreligion, and thank God for that spirit of ceaseless inquiry which impels us to seek truth and truth only, and, when we have found it, to hold it with a grasp whose tenacity cannot be broken.

So then in our daily life as the servants of our suffering fellow creatures, in our eager race after improvements, in our efforts to spread abroad over the earth the results of the knowledge we attain, I hold that the practitioners of medicine of the now closing nineteenth century have not been left behind in the race of life; that we have won our laurels, and have been faithful to our trust. And as we exult in the progress we have made, and are humbly thankful, so let us hope will those who follow after us, outshine our accomplishments and leave us in turn very far behind them in knowledge and in power for good. . . .

I have endeavored to recall to your memory the character, the achievements, and the capability of the practitioner of former times. I have shown you how infinitely greater is the knowledge and the utility of the practitioner of the present day. We know how he has brought every region of the body, even those which were formerly deemed wholly beyond the sphere of his influence, such as the contents of the cranium, the vital organs of the chest, of the abdomen, and of the pelvis, under the dominion of our science; that by the institution of preventive medicine, he has swept away many of the opprobria, and of the direst scourges of former times; and it only remains to indicate in very few words the still vast field of further utility that lies open for cultivation by the practitioners of the future. There is one plague spot, I fear, which even he will fail to conquer; which will remain to fester, to kill its thousands, to maim, disfigure, and to sap the health of millions, of deserving and of undeserving alike, and, as the great curse of humanity, to baffle all our efforts to arrest the progress of disease, and to render them futile and abortive. You know the curse to which I allude; the curse that steadily and vindictively pursues the track of licentiousness, of ungoverned passion, of hateful sensuality; and you will admit with me that so long as human nature remains what it is, and is left in unbridled possession of the means of gratification, no ray of either light or hope will fall on that dark track.

Some day men may have become sufficiently enlightened to submit to necessary legislation and restrictions on this, and cognate subjects; but, until they do, the foul stream of syphilis will continue to meander, hither and thither, and whithersoever it will through the world of life; will poison its springs, will wither even its fairest blooms, and destroy its richest fruits without selection and without mercy.

By the cultivation of bacteriology and cognate sciences, by a deeper and more profound acquaintance with natural phenomena and laws, I can foreshadow in my mind the time when the whole range of zymotic and exanthematous diseases will have been subdued and conquered; when the seeds of each will have been isolated, and so studied that their individuality will be recognizable; the soils in which they will grow, and those in which they will lie sterile will be known and appreciated, and be brought under cultivation by the hands of the medical men of the day; when the methods of dealing with them will be such that they may be reduced to harmless quantities; and when, by the spread of sanitary science, the whole human race may be protected from their evil influences.

It will not be in our day that these mighty triumphs will be won, but our successors will undoubtedly achieve them; and the time will certainly come when the kingdom of disease will be so closely narrowed down that only the necessary accompaniments of the changes and vicissitudes of natural laws, the evils attendant upon the wilful disobedience of those laws, the innumerable accidents to which life and limb must be for ever liable, and the inherent defects and deficiencies in the harmonious working of the parts of a machine so exquisitely and delicately constructed as is the frail body which, for a time, we inhabit will be the only kingdom in which the professors of medicine and surgery will be called upon to exercise their sway. Then will the victory of our science be complete, and the day will have come when the world will be called upon to acknowledge that the labors of the physician and surgeon, patient, enduring, untiring, as they have been through all time, have not been in vain, and have reached their final consummation.

DR. JAMES L. CABELL, Professor of Anatomy and Surgery in the University of Virginia, died at Overton, Va., on the 13th, aged 76. He was graduated in medicine at the University of Maryland, in 1834. During the war he had charge of the Confederate military hospital in Charlottesville. He was Chairman of the National Sanitary Conference at Washington during the yellow fever epidemic at Memphis, and subsequently was President of the National Board of Health.

### INTERNATIONAL COMITY IN STATE MEDICINE.

*Read in the Section of State Medicine at the Fortieth Annual Meeting of the American Medical Association, June 25, 1889.*

BY JOHN B. HAMILTON, M.D., LL.D.,

SUPERVISING-SURGEON-GENERAL U. S. MARINE-HOSPITAL SERVICE.

*Mr. President:*—The last quarantine convention held in this country was held in Montgomery, Ala., March 5, 6, and 7, 1889, pursuant to a resolution of the Alabama Legislature. The conference was largely attended, and although called for the purpose of considering quarantine alone, the meeting resulted in the formulation of some well known principles of sanitation, but which, not having been codified, were, nevertheless, in a somewhat nebulous state. Among other propositions the conference agreed to the following, which I here recite as the text of this paper:

*"Resolved,* That this conference is of opinion that it is a duty devolving on all Nations to take measures to eradicate any plague centre from their territory, and that the existence of such plague centres is a menace to all other Nations, and that our State Department be requested to take measures through proper diplomatic channels for the conveyance of this opinion to the Governments deemed obnoxious to the opinion as herein expressed."

The medical part of International law is a recent creation. The International sanitary conferences that have been held in Paris, Constantinople, Vienna, Washington, and Rome, have successively been the arenas where these questions have been discussed, and so far there has been little result, if we except the International quarantine maintained at the Suez Canal by the French, and the Consular system of notification inaugurated by the United States. At these conferences, with all the conservatism underlying the action of diplomatic representatives, the views of the technical delegates, while not always fully adopted, have not seemed too radical, and the mere fact of the calling together of these conferences, is itself proof that Nations are now acting in formal recognition of the necessity of a new chapter in the International Sanitary Code.

I speak of the "International law," although it is well known that "there is no legislative or judicial authority, recognized by all Nations, which determines the law that regulates the reciprocal relations of States." (Wheaton.) But there are interpretations of the *jus gentium* which, by common acceptance and long usage, have been the guiding principles on which diplomatic disputes have been settled for many years.

Without entering upon the question of whether it is strictly correct to use the term *law* as applicable to mere rules governing the conduct of independent Nations with one another, we may at least admit that there are certain moral obliga-

tions resulting from natural rights, which Nations at peace respect and observe. Mr. Madison defines International law as "consisting of those rules of conduct which reason deduces as consonant to justice, from the nature of the society existing among independent Nations, with such definitions and modifications as may be established by general consent." (Wheaton.)

"To this favor, then, we come at last" in discussing this question, that whatever is done or admitted, is by general consent. Most of the terms of the International law have been settled by treaty.

One of the *absolute* rights of independent States resting upon general consent and common usage, and acknowledged as the most important, is the right of self-preservation. "This right," says Wheaton, "necessarily involves all other incidental rights, which are essential as means to give effect to the principal end." It follows logically, that preservation from epidemics falls within the rule, and a Nation should have a right to view as equal acts of hostility the sending out of a piratical craft, or of a ship infected with yellow fever, cholera or other contagious disease. That division of commerce known as the carrying trade, is too impatient of sanitary restraint, it should be stripped of its power to convey disease, and by International treaties the carrying trade may be so regulated. There need be no interference with shipping. Modern machinery of disinfection has taken the place of "detention." But even this regulation will not go to the root of the evil, for the existence of a plague centre in any country is a constant menace, and the carrying of fomites may sometimes escape the utmost vigilance.

Therefore it seems that the *jus gentium* requires that any Nation, having within its territory an agency capable of destroying or injuring another, suppress that agency. This is not a strained interpretation, for we may find the general principles recognized in the restrictions placed upon a neutral. A neutral must restrain from fitting out, or sailing of armed cruisers of belligerents, and must prevent their territory from being made the base of belligerent operations; not only that, but a reasonable vigilance must be exercised. (Wharton, International Law Digest.) And further it was claimed, and the claim has been admitted, that it is the duty of the sovereign of any country to restrain agencies likely to injure another country, such as by predatory Indians or other marauders, or mob injuries. (Wharton, loc. cit.) The diversion or obstruction of navigable waters without the consent of the injured Nation, has also been successfully claimed as a violation of International rights. Why then should not the claim be insisted upon, that under the absolute right of self-preservation, we shall demand of certain other countries that reasonable diligence in suppressing small-pox, yellow fever and chol-

era be displayed by those Nations owning disease-breeding foyers.

There has been a great increase in the comity between Nations in regard to sanitary matters in the past few years. The first step is clearly that inaugurated by the Vienna Conference of 1874, where the danger of cholera importation having been recognized, by general consent, the French Government took charge of the quarantine service at the southern entrance to the Suez Canal, since which time cholera has not passed beyond Egypt. It is true that cholera appeared in Europe in 1883, but it came by a different route, *i. e.*, by French troop-ships from Tonkin, and the disease was thence disseminated to Spain, Italy, Sicily, Sardinia and South America.

The next important step in International sanitation, I am glad to say, was taken by our own country. Dr. John C. Peters, of New York, in a letter written to the late Surgeon-General Woodworth shortly after a visit to Havana, wrote that "an international public sentiment should be created against the filthy and careless ways of the authorities, which cause so much suffering and death among the mercantile and public navies of the whole world." (Woodworth on Quarantine, Transactions International Medical Congress of Philadelphia, 1876, p. 1068.) That officer (Jno. M. Woodworth) in a report to Congress in 1874, had invited attention of Congress to the necessity for "prompt and authoritative information to threatened ports of the United States of the shipment of passengers or goods from a cholera infected district," and he suggested that the Consular officers of the United States should be instructed to place themselves in communication with the health authorities of their respective localities, and to advise promptly, by cable, of the outbreak of cholera, and the sailing and destination of any vessels carrying passengers and goods from infected districts. This suggestion, so eminently practical, was finally adopted by Congress in the law of April 29, 1878, which now forms the basis of our existing Consular sanitary regulations. Through the kindness of the Honorable the Secretary of State, and the courtesy of the efficient chief of the Consular Bureau, I was permitted to recast the last revision of the sanitary portion of the Consular regulations (1888), and I am of opinion that our regulations on this subject are at present in advance of those of any other country. The *Bureau Consultatif d'Hygiene*, of Paris, in its last report, invited the attention of the Minister of Foreign Affairs to these regulations, and recommended that the French Consuls receive similar instructions. Our government has gone much further in this direction. We have employed a competent inspector in Havana since 1879, who is attached to the Consulate as medical adviser, and who makes personal inspection of the shipping bound to the United States, and who

attends to the sanitary welfare of American vessels in that port. When the cholera became epidemic in Europe in 1883, by my recommendation, a medical inspector was attached to the Consulates at Liverpool, London, Havre, Bremen, Hamburg, Marseilles and Naples, who, under instructions from the Bureau, made careful inspections of emigrants, baggage and merchandise bound to the United States. No government has yet protested against these inspections except Spain, which country took exception to the continued presence of the United States Inspector in Havana, but that powerful country withdrew the objection when it was pointed out that, without such preliminary inspection, under municipal regulations of our ports, the carrying fleet would be greatly delayed, and at some ports shut out altogether during the summer months.

Our National quarantine laws are now much more rigid than heretofore, and year by year the stations are becoming more completely equipped, but much trouble would be saved, and danger avoided, by enforcing the international rule now asked, as a right.

What excuse can exist for apathy in countries where yellow fever and cholera are respectively epidemic? It is not a friendly act for a Nation having a contagion-breeding centre, to fail in the exercise of such vigilance as might prevent the emanation of the disease germs.

I again quote Woodworth (*loc. cit.*). "The endemic homes of cholera and yellow fever are the fields which give the greatest promise of satisfactory results to well directed and energetic sanitary measures, and to this end an international sentiment should be awakened, so strong as to compel the careless and offending people to employ rational means of prevention."

In the volume by Dr. E. C. Wendt, of New York, on "Asiatic Cholera," New York, 1885, I wrote concerning this subject: "A National Government . . . during its existence as a Government, must assume certain responsibilities, among which are those affecting the physical and pecuniary welfare of the people. A Government must, under the natural limitations of human rights, take proper and necessary measures to protect its subjects against pestilence or famine by such wise and prudent acts as the necessities of the time may seem to warrant. A failure so to do would subject such a Government in the eyes of all civilized peoples to just condemnation, and as the safety of Nations makes them mutually inter-dependent, whether they will it or not, so the safety of a particular Nation is dependent upon the physical integrity of its several municipalities, as well as upon the physical integrity of its neighbors. . . . Modern Nations have tacitly recognized these responsibilities, and endeavored to meet them by 'international conferences,' rarely, however, with any

view to mutual concession. At each 'conference' thus far held, the commercial phase of the question has, although purposely kept in the background, seemed to be paramount, and although there has been substantial agreement, first as to the responsibility of any Nation having epidemic disease within its borders that such disease should not be allowed through negligence to afflict its neighbor; and second as to the desirability of a synchronous united effort looking toward final eradication; yet the moment the details by which these desirable ends were to be attained were discussed, harmony was at an end, and so it has happened that each Nation for itself assumes its own responsibilities towards its citizens, and allows its neighbor to adopt in turn such independent measures as in its judgment the occasion warrants.

It is, therefore, clear that international public sentiment must be created to compel these Nations owning cholera and yellow fever centres to no longer afflict the globe by their apathy and indifference to the general welfare.

"Who can doubt that if the action of Russia in respect of the plague, and of the United States in regard to yellow fever, were imitated by Great Britain, Burmah and China, as regards cholera; Spain, Brazil, Central America, Mexico, the West Indies, and the occidental littoral of Africa, in regard to yellow fever, that those two diseases would speedily disappear from the earth."

There is then a plain duty before this great Association which embodies the combined medical wisdom of the United States, and that is to lend its powerful aid toward the humanitarian side of this great question. Let this Section reaffirm the Montgomery resolution, and commend it for adoption by the Association. Its object is to enhance the welfare of humanity, and its accomplishment is within the bounds of possibility.

Washington, D. C., June 15, 1889.

## THE METHOD OF FEEDING IN CASES OF INTUBATION OF THE LARYNX BY POSITION, HEAD DOWNWARD, ON AN INCLINED PLANE.

BY W. E. CASSELBERRY, M.D.,

PROFESSOR OF MATERIA MEDICA AND OF THERAPEUTICS AND OF  
LARYNGOLOGY AND RHINOLOGY IN THE CHICAGO MED-  
ICAL COLLEGE; LARYNGOLOGIST TO THE SOUTH  
SIDE FREE DISPENSARY, CHICAGO.

Since the presentation to the Chicago Medical Society, in September last, of the preliminary verbal report on this method of feeding as just then devised by me, the subject has assumed such importance, and the method, as modified through further experience, has been so successfully practiced within a limited circle, that it is desirable to widely promulgate the device in its perfected and modified aspects.

The unavoidable entrance of food material into

the lower air-passages in process of deglutition has been the most serious drawback to the operation of intubation of the larynx. It has influenced many surgeons to reject or to abandon the procedure in favor of tracheotomy. Others have sought to obviate the danger by strictly withholding liquids—a plan which occasions in febrile patients indescribable agony from thirst, which is not relieved by the substitution of semi-solids and ice. The cry of water! water! water! from these little patients, alike when awake, during sleep, and in delirium, is yet ringing in our ears.

Many and ingenious were the devices to overcome the difficulty: the nasal feeding tube, the rubber epiglottis, the metal epiglottis tube, deep intubation, etc.—none of them adequate, and some of them not a little dangerous.

In June, 1888, through the courtesy of Dr. Frank Cary, I performed the operation of intubation of the larynx in a case of diphtheritic croup. We encountered the usual difficulties in feeding which I had before so frequently experienced. The nasal feeding tube was used with the customary partial degree of success only, ice was given, and still there was an incessant pitiable cry for water. We were much distressed on this account, and in despair for some expedient whereby liquid could be administered, it suddenly occurred to me to stand the child on its head and let it drink. A moment's thought sufficed to modify this radical position to one in which the inclination of the body head downward was just sufficient to prevent gravitation of liquid through the tube into the trachea, and to cause, rather, any portion which had been forced into the end of the tube during pharyngeal deglutition to flow back into the pharynx. By action of the pharyngeal and œsophageal muscles the liquid, of course, could be swallowed upward equally as well as downward, just as happens when one drinks, when leaning far over, from a spring.

In this position, illustrated in Fig. 1, the child would suck through a rubber tube from a glass and swallow without the slightest difficulty all the liquid which it desired.

In another case, treated through the courtesy of Dr. Frank Billings, a metal epiglottis tube was inserted, and an opportunity was thus afforded of testing the efficacy of the lid alone. In the upright position, with the epiglottis tube *in situ*, the patient could not swallow water or milk without coughing, indicating entrance into the trachea; while in the inclined position, head downward, it drank freely without difficulty.

The same degree of success has since obtained in other cases. Many of the younger patients will suck more readily from the nipple of an ordinary feeding bottle, although an open tube from a glass is the more rapid means with older children. A few have been found to swallow better

when fed, on the same principle, in the inclined abdominal decubitus; but the inclined dorsal decubitus is usually to be preferred, on account of the facility in assuming the position and of the greater certainty in maintaining a proper angle, although it is largely a matter of suitability to the individual case, whether the child should be inclined on the back, the abdomen, or even on the side. Some surprise is occasioned from the simplicity of the matter, that it had not previously been adopted. Two or three thousand cases had now been treated by intubation, and in all the necessity for a method such as this must have been apparent, but exhaustive inquiry has failed to elicit a previous use of the device in connection

with intubation of the larynx, notwithstanding the publication by Dr. R. Norris Wolfenden,<sup>1</sup> in 1887, of a note entitled "A Simple Method of Procuring Deglutition when such is Impeded by reason of Extensive Ulceration of the Epiglottis," in which he described a patient suffering from the tuberculous ulceration of the larynx, who could swallow not more than a teaspoonful of liquid at a time, and "this only at the cost of much pain and terrible paroxysms of coughing," who had learned for himself and subsequently demonstrated to Dr. Wolfenden, the "wrinkle" of lying stomach downward upon a couch, with head and arms hanging free over the end, in which position he could drink a large tumblerful of water with the greatest ease and comfort.

<sup>1</sup> The Lancet, July 2, 1887. The Journal of Laryngology and Rhinology, August, 1887.

Regarding the exact position, an angle of inclination of  $20^\circ$  is suitable to most cases, although this may vary slightly in either direction.

During the process a little fluid will gravitate into the naso-pharynx, to remove which the child must be made to swallow three or four times after the vessel of liquid has been taken from its mouth, and before it is permitted to regain the erect posture, otherwise this naso-pharyngeal residuum will gravitate through the tube and excite cough.

The patient can be inclined without inconvenience for a minute or more, although less time will suffice.

One element of danger, "*schluck pneumonia*," and a vast amount of deprivation and suffering are thus removed from the operation of intubation of the larynx, which, freed from the odium attached to these disadvantages, must become more general and exhibit better results; not that the entrance of food material into the lungs is the sole cause of pneumonia occurring in the course of diphtheritic laryngitis, for this complication frequently arises apparently by simple extension of the diphtheritic inflammation downward, and occurs, at times, after tracheotomy, when deglutition is unimpaired. Indeed, in 116 autopsies of intubation cases, presumably fed in the upright position, recorded by Dr. Northrup, of New York, not a particle of food could be found in the bronchial tubes, which would seem to prove the danger of pneumonia by aspiration to have been over-estimated; but as water and milk, the materials most likely to enter, would be the most difficult of identification after death, aspiration of them in considerable quantity must still be regarded as an exciting factor, and one which is capable of originating pneumonia in the absence of other causes.

Since it is now conceded that the use of rather small and loose tubes is preferable to tight fitting ones, the danger of their slipping out while in the inclined position cannot be disregarded. The liability is minimized by using an angle of inclination the smallest that will accomplish the desired result. Feeding unaccompanied by cough is then less likely to result in dislodgement of the tube than when the erect position is maintained and violent expulsive cough is excited at every act of deglutition.

Since June, 1888, Dr. E. Fletcher Ingals has nourished thus, very successfully, five cases, and Dr. F. E. Waxham has reported thirty cases, in all except two of which, he informs me, feeding was accomplished without difficulty by this means. Of this series he saved 50 per cent., an excellent result, to which, doubtless, the improved method of feeding contributed in large measure.

70 Monroe Street, Chicago.

## ON THE PASSAGE OF PORTAL BLOOD INTO THE GENERAL CIRCULATION, AND ITS PROBABLE RELATION TO TOXÆMIA.

*Delivered in the Section of Practice of Medicine, Materia Medica and Physiology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY CHARLES G. STOCKTON, M.D.,  
OF BUFFALO, N. Y.

The coma which occurs in some cases of cirrhosis of the liver never has been explained satisfactorily. It has been ascribed to a form of toxæmia, but just why there should be a toxæmia presenting such a history it is not easy to understand. This is but one of many interesting symptoms, the origin of which is attributed to toxic conditions of the blood—a subject just now receiving much attention.

One view of the matter appears to have been overlooked, and to this I ask your attention. It is the current opinion that the blood from the portal vein before it is fitted for the general circulation must first filter through and be modified—refined—by the liver. When the liver is congested and there is overfullness of the portal vein it doubtless happens that the blood traversing the liver is imperfectly acted upon by the hepatic cells and as a result irritating, toxic substances enter the general circulation, producing those symptoms known as biliousness. That this inadequacy of the liver does occur there is abundant authority to uphold, and I have no argument against it. On the contrary it is contended by the writer that to whatever extent the liver fails to metamorphose the portal blood, to just that extent the blood departing in the hepatic vein is of the nature of portal blood, and is likely to induce systemic derangement.

We now come to an important proposition: It is that there exists inosculation of the branches of the portal with the systemic veins, which permit the flow of portal blood into the general circulation without having passed through the liver at all. Some of these inosculations are normally present, some of them are anomalous, and still others result either from diseases of the liver itself or from inflammatory processes involving its capsule and other surrounding structures.

Of those inosculations which are normally present, one of the best known is that which occurs in the hæmorrhoidal plexus, formed by tributaries of the inferior mesenteric, which terminate in the internal iliac. "The portal and general venous systems have a free communication by means of the branches composing this plexus."<sup>2</sup> Besides this there are anastomoses between the portal vein and branches of the vena cava; between the gastric and the œsophageal veins; between the left renal and veins of the intestine; between superficial branches of the portal and the phrenic veins;<sup>3</sup> [recognized by Tiernan and found

by Freirich to exist in every case in which he had injected the portal :<sup>4</sup>] between the epigastric, *et al*, and branches of the portal, as first described by Sappey,<sup>5</sup> an anastomoses which probably is the same as that described by Luscha, [Anat. II, p. 339] as the *vena parumbilicalis*, and which he claims occurs in man and most mammals as a normal condition.

Schiff found that the circulation persisted in the liver after ligating the portal vein and the hepatic artery, and explained the fact by the entrance of blood through the para-umbilical veins.<sup>19</sup> Finally, Lauder Brunton<sup>20</sup> states that a portion of portal blood, by collateral circulation, enters the systemic veins without entering the liver. Now as to those intercommunications which occur as anomalous and somewhat rare conditions, there are reported to medical literature many well-authenticated cases. A branch of the portal communicating with the iliac vein is reported by Giacomini.<sup>6</sup> Another remarkable case is reported by Sperino.<sup>7</sup> Hyrtl<sup>8</sup> relates an instance of the union of the splenic vein with the vena azygos. In a very interesting article by F. Champneys<sup>9</sup> reference is made to a large number of similar inosculation, normal and anomalous, mentioned by Henle, Rokitansky, Cruveilhier, Mérière, Serres, Reynard and others. Further data bearing on this point may be found in the writings of J. H. Russell,<sup>10</sup> Mérière,<sup>11</sup> Peygot,<sup>12</sup> Burow,<sup>13</sup> Bamberger,<sup>14</sup> Klob,<sup>15</sup> Schulze,<sup>16</sup> and Monro.<sup>17</sup>

The fact that such intercommunications are established as a result of cirrhosis of the liver and other diseased conditions obstructing the ordinary current of portal blood, is attested by so much evidence that citations here are less necessary. In some instances there appeared such marked varicosis that the current in the vena porta was reversed, the congestion of the viscera relieved, and the ascites, previously existing as a striking symptom, was made to disappear. This passing away of ascites has been noted by many clinicians, and has generally been attributed to the causes mentioned, although it should be stated that portal systemic anastomoses of considerable size often exist while the ascites remains present. F. Champneys<sup>9</sup> relates an interesting case wherein dropsy subsided owing to anastomosis, and parallel cases reported by Sappey, Hoffman and Hanot, are cited by Thierfelder,<sup>18</sup> and, on the other hand, the same author accounts for the œdema of the lower extremities, and a relatively early œdema of the abdominal integument, by the back-flowing of the portal blood into the crural veins and epigastric veins respectively, thus impeding the return flow of venous blood to the center. It would seem highly probable that in those cases in which, after frequent tapping, the ascites entirely disappears, as stated by Flint<sup>19</sup> and others, the reason is to be found in the establishment of collateral portal circulation.

Anatomical evidence that collateral portal circulation is set up in cirrhosis of the liver, is extensive ; amongst other authorities may be mentioned Gubler, Lyons, Virchow, Monneret, Renaud and many besides these. It is also well known that after peri-hepatic inflammation there frequently remains adhesions which unite the liver and diaphragm to such an extent that, through many small inosculations, there is a free communication of blood from one to the other. Such unions from inflammation are not rare, and it would seem that after examining the testimony all must admit that portal blood may pass around the liver and join the blood in the systemic veins, thus escaping those elaborate changes which the liver is supposed to bring about in the blood coming from the organs of digestion ; furthermore, it would seem as though this fact were, by normal anatomical arrangement, made possible to some extent in healthy individuals ; and it appears that in some anomalous and pathological conditions the communicating passages are so extensive that torrents of portal blood may enter the general circulation in the manner described.

Let us now pass to the consideration of the second proposition, namely : The blood of the portal vein is toxic. The liver intervenes and, acting the part of a physiological quarantine station, hinders the admission of disqualified material and hence prevents toxæmia. That the portal blood varies in its toxicity there is ample proof, but that it is generally unfit for systemic circulation there is every reason to believe. In the labors of Claude Bernard, Hegar, Schiff, Lautenbach, Jaques, Brunton, Roger, Bouchard, Gautier and others, affirmation of this statement is to be found. Peptones were discovered in the portal vein, and these substances when injected into the circulation were found by Ludwig, Schmidt, Muhlheim and later observers to be poisons.

Hegar, in 1873, found that nicotine when made to pass through the liver disappeared from the economy ; Schiff, in 1877, found this true of other alkaloids ; and Jacques, in 1880, found that some were destroyed in the liver and that others were stored up by the gland, at some later day to pass into the circulation, or to be excreted. Since the studies of Bouchard, Gautier, Vaughan, and others relating to animal alkaloids and extractives, we are better prepared to understand the real nature of the toxic substances which the liver is made to resist or modify, and we now more readily perceive how intestinal fermentation on the one hand, and intestinal antiseptics on the other, excites or retards the auto-intoxication well known to exist under certain conditions.

G. H. Roger,<sup>22</sup> in a thesis published at Paris in 1887, relates the results of numerous experiments as to the toxicity of the blood, in which he shows that the blood of the portal vein is far more poisonous than that from other sources ; and he further-

more shows that the "supra-hepatic blood"—that is, blood immediately after leaving the liver—while far less toxic than that in the portal, is more toxic than that which circulates in the other veins. To this matter we shall after a time recur. It would seem unnecessary to devote further time here to the demonstration of a theory which is pretty well determined.

Having shown that the blood of the portal vein finds more or less ample channels for flowing into the general circulation without passing through the liver, and having shown that the portal blood is always more or less toxic, and sometimes intensely so, it is now incumbent to answer the natural inquiries, first, Why is it that there is not in all individuals an ever-present toxæmia, occasionally reaching a dangerous, or even fatal degree? And second, Why is it that when free anastomoses occur as a result of cirrhosis of the liver or other affections, coma, delirium, diarrhœa, propeptonuria and glycosuria do not occur as persistent symptoms? Admittedly these questions must be answered, and in turning to the reply let us first consider the next proposition, which is: Normally there exists in the portal vein a lower blood pressure than in the systemic veins. It will be seen that as a natural result of this, instead of the portal blood coursing into the systemic veins, in health the systemic blood would find its way into the vena porta. The low pressure in the portal vein is doubtless determined by the pump-like action exerted on the liver by the diaphragm during respiration, and by the fact that, unlike the veins of the general system, the branches of the portal lack the support and pressure of the muscles. However it comes about, it is maintained, as stated by Lauder Brunton,<sup>21</sup> that the blood-pressure in the portal vein is very low.<sup>22</sup>

Is it not reasonable to suppose, then, that this difference in blood-pressure is the means by which nature protects the system from the toxæmia which would probably follow the free passage of portal blood into the general circulation?

There can be no question, however, but that when the anastomoses are very large and numerous, the inflowing systemic blood would soon practically equalize the pressure, but even in these cases the tendency would be towards the portal current and not away from it, save in instances of obstructive liver disease or the equivalent. So it would appear that under ordinary circumstances toxæmia would not result from even free anastomosis.

But extraordinary circumstances occur. From indiscretions in diet, from sedentary habits, from the irritation of drugs, or from exposure there supervenes a congestion of the liver, an obstacle to its circulation; from this impediment to the portal stream there is established an unusual portal pressure, a pressure greater than that in the

systemic veins. Naturally the portal blood freighted with its peptones, its bile, its animal alkaloids and all its poisons, finds its way in greater or less proportion into the general circulation and toxæmia is the result. How often are there cases accompanied by hæmorrhoids, tenderness over the hepatic region, languor, a coated tongue, anorexia, headache and the multiplicity of toxæmic symptoms; how often do we give cathartics to deplete the portal circle; and how often success follows our measures. Certainly such experiences are suggestive, but they are not so conclusive as are those which we have in cases of cirrhosis of the liver, when the portal vein is always found distended, when from collateral circulation the neighboring veins are enlarged—when from anatomical<sup>24</sup> as well as from physiological reasons we may be sure there is a blending of the streams.

And finally, when ascites disappears and the other signs and symptoms of cirrhosis continue, the most doubting must confess that here, indubitably, the portal blood invades systemic veins, and produces certain results. To name these results would be to mention many of the symptoms of hepatic cirrhosis, the most striking of which is that one spoken of in the beginning of this paper—the coma of cirrhosis—a symptom for which J. Hilton Fagge confessed himself unable to account.

But, I have been asked, why is it that this symptom is so rare in a disease which is so common? Why is it that patients do not present symptoms of intense toxæmia more persistently? Why is it that acute symptoms follow a temporary obstruction of the liver while insignificant symptoms attend a chronic obstruction? In reply I would suggest that this is quite parallel to what ordinarily happens in other acute and chronic maladies; that the organism gradually accommodates itself to circumstances. A further answer may be found in the following proposition, viz.: When the integrity of the blood is not seriously diminished it is equal to the metabolism of nutritive substances, and to the destruction of toxic substances, coming to it under certain conditions. Any man may satisfy himself of this by remembering well-established facts in physiology. The blood in the hepatic vein is more poisonous than that in the vena cava. After a meal it contains glucose, fat, albumens, and sometimes peptones. Further along in the veins they disappear; what has become of them?

The thoracic duct carries besides fat, proteids, glucose, extractives, etc., to the vena cava. They disappear in the blood; and one must admit that this fluid has a function of assimilation and dissimilation that reminds a person wonderfully of the liver. Perhaps we do not sufficiently recognize how the organs lend and borrow; and that neighborly kindnesses in services rendered exist

inside as well as outside of us. At any rate, proof of this function of the blood can be seen unmistakably in what takes place in the portal vein: for, whereas at its beginning it, during digestion, is found loaded with peptones, these, in good health, have almost entirely disappeared before reaching the liver. It is apparent that these statements must pass unchallenged, and so, I think, will the proposition.

Now it seems to me that the blood is for a period able successfully to oppose, and partly to appropriate that which the portal empties into it: but there comes a time when its integrity is diminished, when its resistance is overcome, and then its toxicity in one respect or another becomes such that definite symptoms thereof become apparent. It would be interesting, perhaps, in this connection to make some reference to lithiasis, glycosuria, transient albuminuria, etc., and to those individuals who, during life, are cachectic, splenetic, and sick, but who show on autopsy no lesions which adequately explain the condition: but circumstances will not permit.

275 Franklin St., Buffalo, N. Y.

#### DISCUSSION.

DR. J. H. MUSSER, of Philadelphia, congratulated Dr. Stockton on the very ingenious arguments he produced to maintain his thesis. The question, however, obtains so much of a physiological aspect that he felt quite incompetent to discuss it. Clinically he had never seen any cases of hepatic coma, so-called, or the coma of cirrhosis, that could not be accounted for either by cholæmia, uræmia, or a toxæmia due to loss of function of the liver. This, of course, was only his experience. He would state that in all cases of hepatic coma there was either pneumonia, active congestion of the lungs, or some inflammatory condition, however small, sufficient to overthrow the balance of the economy, and hence disturb the functions which destroy any deleterious matter in the blood, if such is the power of that tissue, or to interfere with glandular activity by which ptomaine-poisoning or the like is made possible. Such disturbance of the circulation and nervous system as a local inflammation induces coma will

cause such changes of function as Dr. Stockton argues to arise from other circumstances.

DR. OSLER, of Baltimore, thought that the point referred to by Dr. Stockton is one of serious import. He was not sure, however, but that it is only partially true. He doubted whether the question thus received its solution. He believed that the collateral circulation is a constancy. This must meet the blocking up of the channels. The same condition obtains as in narrowing of a valve of the heart. Every one has found in post-mortem examinations, extreme cirrhosis of the liver without a single symptom during life, and yet in such instances a great proportion of the portal blood passed into the general circulation. Furthermore, in cases of fibroid obliteration of portal vessels, the portal blood for years passes through the circulation.

DR. TREMAINE, of U. S. A., thought that the essayist had made a mistake in regard to the portal circulation: it is part of the venous circulation only interposing the liver. The purposes for which the venous blood passes through the liver are not clearly understood. He would rather explain the results by a defect on part of the action of the cells, whose office it is to eliminate the toxic elements.

DR. H. A. HARE said that he thought perhaps Dr. Stockton had lost sight of the more recent studies of Schiff and Lautenbach, viz.: that any capillary network is capable of rendering blood containing toxic substances innocuous. The lungs, for example, are similarly destructive agents. Capillaries are oxidizing agents *per se*, as a shallow pebbly brook is an oxidizing agent. That oxidation does occur is proved by the high temperature of the blood leaving the liver. Further, all peptones are not poisonous, but it is rather the pana-peptone, or hemi-albumose, which is abnormally absorbed and caused toxæmia. Peptones are normally absorbed, and predigested food by the rectum ought to cause toxæmia if all peptones were poisonous. Again, the argument of Dr. Stockton is faulty since the inoculations are constant and the toxæmia is rare.

DR. STOCKTON, in reply, said he felt much gratification over the discussion to which the paper had given rise. He did not consider that the

<sup>25</sup> I am permitted to mention a series of experiments made by my colleague, Prof. Julius Pohlman, of Buffalo, demonstrating that in each of a number of dogs examined—some while fasting, some just after eating—some between fasting and feeding—the blood-pressure of the portal vein was far below that in the systemic veins. During digestion the portal pressure was increased, but it was never near the pressure in the systemic veins. These experiments will be published.

criticisms, in the main, were contrary to the claims made in the paper. Notwithstanding the late investigations mentioned by Dr. Hare, the fact remains that peptones disappear in the blood without passing through a capillary network. The claim made that the blood-pressure in the portal vein is lower than in the systemic veins, thus making a protection to the systemic circulation, was not spoken of. This should be explained. When the portal pressure becomes the higher, toxic conditions appear; and but for the action of other organs than the liver, and of the blood to purify itself, more conspicuous symptoms would appear. When the resistance of the blood fails, then toxic symptoms do occur.

## MEDICAL PROGRESS.

ON A NEW DIURETIC IN HEART DISEASES.—Experiments and investigations made by M. GERMAIN SÉE (Paris) concerning the effect and value of milk in heart diseases, have led to the following conclusions:

1. Lactose constitutes at the same time the most powerful and the most inoffensive diuretic. It alone imparts to milk its diuretic properties. The other principles of milk, especially the water and the salts, have no manifest or useful effect, the chlorate of soda does not add anything to the polyuria, which is due to milk sugar, and even the salts of potash have but a limited action.

Milk taken in quantities of 2 litres causes diuresis, but in quantities of 4 litres (each of which contains 50 grams of lactose) it induces at the same time a pronounced glycosuria, a transitory diabetes, as a quantity of 200 gr. of sugar thus absorbed is eliminated by the urine. At the same time a considerable excretion of urea indicates a destruction of the albuminates. There is consequently glycosuria and azoturia at once.

Milk sugar renders it possible to avoid these inconveniences and dangers. One hundred gr. of lactose in a draught produce an enormous diuresis which we are not sure to obtain with 4 or 5 quarts of milk. With the lactose there is neither glycosuria nor azoturia. In milk the effect of lactose is impeded by caseine and fat.

2. The polyuria resulting from the internal use of 100 gr. of lactose exceeds all the other artificial polyurias; it increases rapidly to 2½ litres, and almost constantly rises to 3½ and even to 4 and 4½ litres on the third day. Then it remains stationary or decreases to 2½ litres for several days. During that time the dropsical symptoms disappear with almost absolute certainty, the blood is freed from hydrates, and this is the reason why the diuresis is no longer as intense as at the beginning of the treatment. But after a few days of rest another dehydration of the blood and

resorption of dropsical accumulations may be obtained in the same way.

3. Effect on dropsy of cardiac or renal origin. It may be said that lactose has a sure effect on dropsy of cardiac origin, but its action is doubtful or even nothing in dropsy of renal origin. In affections of the heart it fails only in cardiacs where the kidney is affected with Bright's disease, and when the albumen increases to 0.60 or 1 gr. per litre. As long as the quantity of albumen is small the result is favorable, which leads to the supposition that in these cases there is no renal lesion, but simply a stagnation of the blood. By diuresis from lactose the degree of alteration in the kidney may also be measured.

4. Time for the cessation of the diuresis. Administration of lactose. Sometimes the diuretic action is found to be interrupted by causes other than lesion of the kidneys. A diarrhoea may ensue which naturally diminishes the diuresis. In other cases the patients have for a longer or shorter time profuse sweats or accidental transpirations which diminish the polyuria, but it soon reappears.

The medicine is generally well borne. It should be given for eight or ten days, which would suffice to bring about a noticeable dehydration of the blood; then a pause is made of a few days, when its administration may begin again. The lactic draught is somewhat insipid, but its taste may be improved by adding a little brandy or peppermint. In all cases it is of importance to diminish or even to stop all other drinks, including bouillon and especially milk, which becomes useless as a diuretic, and encumbers the stomach and impedes digestion of other nourishments. Also in this respect lactose has great advantages, as it permits the patient to eat all kinds of food, even meats, which are often indispensable to sustain the sinking forces of a cardiac patient who has arrived at the last stages of the disease.

5. How lactose acts. Therapeutic comparison with other diuretics. The above facts being known the question arises concerning the mode of action (which might be called physiological) of this new diuretic. We know that diuretics often act through the high blood pressure which they cause, but with the present substance pulse and pressure are not altered. The alkaline salts are credited with producing the diuresis by virtue of their osmotic power, and especially the salts of potash possess this. But we do not obtain any better results by adding 2 gr. of potash to each litre of lactose portion than by the lactose alone. As the latter does not pass the kidneys it can act only through osmosis, and we must admit an elective and selective action of lactose upon the secretive elements of the kidneys; it is a renal physiological diuretic.

On comparing it with the other diuretics we find the following: Those which augment the blood pressure, the cardio-vascular substances, to wit: digitalis, convallamarine, strophanthus, act

much more feebly, less surely and less effectively upon dropsy than lactose. Bucquoy, with his well-known honesty and genuine scientific mind, has recognized its superiority in this respect to strophanthus, which he himself had favored.

A second group of diuretics, the only one thoroughly established so far, comprises the renal diuretics proper, in the first place caffeine. It forms part of a chemical series which begins with xanthine, includes theobromine and ends with caffeine, the most methyled of these substances. It is already known:

1. That caffeine and theobromine are renal diuretics like lactose.

2. That both of them act independently of vascular pressure, for one may cut the vaso-motor centres and destroy the vascular nerves without hindering in any way the caffeine diuresis.

3. That they have no tonic effect upon the heart, as was supposed, and in this regard they likewise resemble lactose. But caffeine causes nervous and cerebral troubles unknown to lactose.

6. We possess, therefore, in lactose, the diuretic for heart troubles at the asystolic period, the genuine cure for dropsy of cardiac origin, even for those kinds of dropsy which resisted other polyuric agents. In asystole there is another extremely dangerous accident liable to occur—dyspnoea; against this lactose is powerless, so it must be aided by iodide of potassium. This substance constitutes through the iodide and the potassium the proper medicine for heart and circulation. It lacks only diuretic power. To meet all indications iodide should be combined with lactose.—*Le Bulletin Médical*, No. 47, 1889.

**DIAGNOSTIC SIGNIFICANCE OF INCREASE OF THE KNEE PHENOMENON AND OF THE FOOT CLONUS.**—In an interesting article on this subject by TH. ZIEHEN, published in the *Corresp. Bl. des Allg. ärztl. Vereins von Thüringen*, No. 1, 1889, the author arrives at the following conclusions: An increase of the phenomenon in both knees may be regarded as morbid, and significant only if foot clonus exists at the same time. An increase of the phenomenon in one knee only is always a symptom of disease. In healthy adults foot clonus is extremely rare, consequently a pathological symptom. In children, even when healthy, foot clonus occurs parallel with a physiological increase of the tendon phenomenon; especially in early years increase of the knee phenomenon seems the rule. For adults the following holds good: Foot clonus not accompanied by other marked objective symptoms is indicative of epilepsy or neurasthenia; with hemianæsthesia of the sensitive nerves; of hysteria; in acute atrophies of amyotrophic lateral sclerosis; with simultaneous intestinal trembling of multiple sclerosis; foot clonus with spastic-paretic walk of spastic spinal paralysis and progressive paralysis; with disturbance

of speech and idiocy of progressive paralysis, multiple sclerosis and epilepsy; with anæsthesia and paralysis of the lower half of the body; of dorsal and cervical meningitis. Foot clonus on one side with hemiplegia or monoplegia of one leg indicates a cerebral organic or hysterical affection more frequently than a spinal organic affection.—*Wiener Medicinische Wochenschrift*, No. 33, 1889.

**REGARDING THE CENTRES OF INNERVATION OF THE SMALL INTESTINE.**—J. PÁL and J. E. BERGGREN studied in Stricker's laboratory the changes in the peristaltic movements of the intestines under the influence of vagus irritation on dogs poisoned with curare, and found (*Med. Jahrbücher*, 1889) that the movement of the small intestine (jejunum and ileum), after irritating the peripheral vagus pedicle, did not ensue regularly until the spine had been cut in the neck. They inferred from this that by cutting the spine in the neck impediments are removed which prevented the peristaltic movements before cutting. Further experiments showed that the obstructing fibres extend through the medulla oblongata and as far as the gyrus sigmoideus. From the fact that after cutting brisk injection of the intestine followed, the authors concluded that vascular nerves run alongside these inhibiting fibres. The irritability of the duodenum from the vagus does not follow that of the jejunum, but that of the pylorus region of the stomach, as previous experiments have shown.—*Wiener Med. Wochenschrift*, No. 23, 1889.

**ON THE DISTINCTION BETWEEN KOCH'S BACILLI AND THE BACILLI OF FINKLER-PRIOR.**—M. SCHENK (Vienna) tried to raise microbe cultures on the albumen of the lapwing eye, and succeeded in discovering differences in the evolution of microbes the distinctive character of which had not previously been found. So the cultures of Asiatic cholera (Koch) and of cholera nostras (Finkler-Prior), which had not appeared so far to be different, acted differently on albumen of the lapwing eye. The bacillus of Finkler-Prior liquefies and discolors the centre of the culture, whilst that of Koch leaves it intact.—*Le Bulletin Médical*, No. 45, 1889.

**ON HYSTERICAL COXALGIA.**—M. BALLET presented to the Société de Biologie a patient who had all the symptoms of a genuine coxalgia: flexion with slight abduction of the thigh, atrophy of the muscles, etc. It was only a case of hysterical coxalgia, however; the remains of an ancient hemiplegia of the same nature, resulting from excessive use of alcohol. This fact is interesting, since it proves once more that hysterical paralysis may be accompanied by atrophy.—*La Semaine Médicale*, No. 27, 1889.

SATURDAY, AUGUST 24, 1889.

THE FORMATION OF GALL STONES.

The rationale of the formation of gall stones is not well understood. We know they are usually formed in the gall-bladder, and they may also form in the common, the cystic, the hepatic duct, and in the intra-hepatic ducts. They occur most often in the female, and usually in middle life. Sedentary habits and local peculiarities of climate are seemingly predisposing causes. Taurocholic acid or taurocholate of sodium is the agent which holds the solids of the bile, cholesterin, biliary pigments, lime, salts, etc., in solution. Why these solids should be precipitated to form calculi is the point in doubt. Foreign bodies in the biliary passages will form nuclei for calculi, and calculi with parasites, fruit seed, particles of mucous have been found in the ducts, but rarely, if ever, in the gall-bladder. Evidently other causes must exist. It is known that fermentation of the bile will cause a precipitation of its solids. Retention of the bile in the gall-bladder and ducts, from any cause, will render the bile less fluid by the absorption of the watery portion, and favor precipitation of the solids. F. MARCHAND (*Deutsche Med. Wochenschrift*, 1888), believes that tight lacing and the corset liver (*Schnur Leber*), is the cause of the more frequent occurrence of biliary calculi in the female. In many post-mortem examinations he has verified his observation. The pressure of the corset or waist-band is applied over the neck of the gall-bladder or cystic duct, causing retention of bile, and consequent condensation of it. A rough

condition of the mucous membrane of the biliary passages and gall-bladder will also favor the formation of calculi. Carcinoma of the gall-bladder or ducts is usually complicated with calculi. This formation in carcinoma is also due doubtless to retention of bile.

Catarrhal inflammation of the biliary passages is said by most authorities not to predispose to, or cause, the formation of calculi. That this is an erroneous idea is proved by clinical evidence. In chronic catarrhal duodenitis or gastro-duodenitis the biliary ducts often become involved, causing sufficient retention of bile to so condense it that perfect casts of the common bile duct are often found in the fæces. That such casts are not oftener found is doubtless due to the non-examination of the fæces. It is fair to infer that a chronic catarrhal inflammation may extend from the bowel through the ducts to the gall-bladder. With such an inflammatory progression, would naturally go the fermentative germs of the bowel. Such a condition would directly favor the precipitation of bile solids in the gall-bladder; that is, retention from partial or complete temporary occlusion of the hepatic duct, and fermentation of bile through the zymogenic germs from the bowel. The increased mucus in consequence of the inflammation would also be present to form nuclei. Chronic catarrhal duodenitis is a very common disorder, and occurs more frequently in females than males, probably because females take relatively more of the hydrocarbons than males.

SUGGESTIVE THERAPEUTICS.

Very little scientific attention has been given to hypnotism in this country, and an opportunity is now presented to American physicians to become acquainted with the subject as presented by DR. H. BERNHEIM in his treatise on the nature and uses of hypnotism, which has been recently translated by Dr. Christian A. Herter, of New York. The hypnotic state, according to Bernheim, is not the exclusive lot of rare neuropathic cases. According to Liébault one-fifth or one-sixth of all subjects are hypnotizable, and while some of the susceptible are hard to hypnotize, most of them can be overcome by a little perseverance and determination on the part of the operator. The hypnotized person is by no means a lifeless

body, or one in a state of lethargy, as some may imagine; though he is inert he hears, is conscious, and often shows signs of life. He may laugh, or try to smother a laugh. He may remark upon his condition. He sometimes pretends that he is cheating, or that he is trying to be obliging. The majority, however, feel that they are influenced; that they are in the power of the operator. Hypnotism manifests itself in different ways in different subjects. There may be simple drowsiness, or other induced sensations, as heat, pricking, etc. This is the lightest influence. When the suggestion affects motility there may be more marked effects, the cataleptic condition may be developed, there is inability to move, and there are contractions and automatic movements. When the suggestion affects the will and causes automatic obedience it is still more decided. All these manifestations of motion, will, and even sensibility, says Bernheim, can be affected by suggestion with or without sleep, and even when it is powerless to induce sleep. In a more intense degree suggestion produces sleep or the illusion of sleep.

To define hypnotism as induced sleep, says Bernheim, is too give too narrow a meaning to the word; such a definition overlooks the many phenomena that suggestion can bring about independently of sleep. Bernheim defines hypnotism as the induction of a peculiar psychical condition that increases the susceptibility to suggestion. It is often true that the sleep that may be induced facilitates suggestion, but it is not the necessary preliminary. It is suggestion that rules hypnotism. Suggested sleep does not differ from natural sleep. The same phenomena of suggestion can be obtained in natural sleep, if one can succeed in putting one's self into relationship with the sleeping person without awakening him. The new idea that Bernheim proposes concerning the hypnotic influence, the wider definition that he gives to the word hypnotism, permits us to include in the same class of phenomena all the various methods that, acting upon the imagination, induce the psychical conditions of exalted susceptibility to suggestion with or without sleep. Such is the case with fascination induced by a brilliant object, or by the gaze. Some subjects submit to the influence without sleep; they are susceptible to suggestions in the waking states. They remember afterward what they have done,

and do not know why they were unable to keep from following and gazing at the operator. Others do not remember what has happened; they have been in a somnambulistic state with the eyes open. In this somnambulistic fascination catalepsy and hallucinations may be induced, often by a simple word, a gesture, or a position communicated to them without previous fascination.

Various phenomena are manifested or may be induced in hypnosis. Nervous subjects sometimes have muscular twitchings of the limbs and febrillary contractions of the face while asleep; but the majority are inert, or become so after suggestion. Sensibility is more or less modified; in light sleep it is preserved; in deep sleep it is diminished or totally destroyed. In a few cases the hypnotic insensibility is enough to enable the most difficult surgical operation to be performed; but hypnotism can by no means take the place of ether and chloroform. Changes in motility are more easily induced than changes in sensibility. But a deeper degree of hypnotic suggestion is required for the induction of automatic movements than for simple catalepsy. Suggestion also induces paralysis as well as contracture. This suggestive paralysis has special characters, which may be distinguished from other paralyses of organic origin. At the will of the operator general sensibility and the special senses may be modified, increased, diminished, or perverted, and in the advanced degrees of hypnosis all illusions and hallucinations may be successfully carried out with great precision, and all actions that the operator commands are successfully carried out.

According to Braid the pulse and respiration are at first slower than normal in hypnotism; but as soon as the muscles are put into activity a tendency to cataleptiform rigidity is produced, with increase of the pulse-rate and rapid and laborious respiration. Heidenhain noticed an augmentation of the salivary secretion, and Tamburani and Seppili noticed that at the time of the transition from the waking condition to the hypnotic state, the respiratory movements became irregular, unequal, and more frequent, the cardiac and vascular pulsations increased, and the face was congested. But Bernheim claims that these symptoms are not induced in patients hypnotized by the quiet method of suggestion, who retain their mental tranquility; nor by those that having been al-

ready hypnotized several times go to sleep with confidence and without emotion or agitation. Suggestion may act upon the vaso-motor circulation; a red spot may be produced upon the body by suggestion, or even a blister may be raised, and hæmorrhages and bloody stigmata may be induced. Bernheim suggests that experiments might be instituted to determine to what degree imagination may influence certain functions in the waking condition. We know that micturition and defecation are greatly influenced by the will, idea, and imagination. By concentrating the mind upon the phenomenon, can we not also produce an increase of heat in certain regions of the body, perhaps even without hypnosis?

That hypnotic suggestion is a valuable therapeutic agent there can be no doubt. It has been employed successfully in organic affections of the nervous system. True the results obtained are often transient; but even a brief respite from the troubles of organic nervous affections is a blessing to the patient. Even in chronic and incurable affections suggestive therapeutics is not useless. It is of undoubted value in hysterical affections. It is important that the suggestion be varied and modified according to individuality, and its efficacy varies according to the subject and the circumstances. It has been found useful in various neuropathic affections, in epilepsy, insomnia, repeated headache, gastric and general neuroses, neuro-arthritis, rheumatic and nervous pains, melancholia, anorexia, writer's cramp, etc. Bernheim does not claim that hypnotic suggestion is a cure-all. He has written an interesting and instructive book upon a subject that deserves careful study.

#### CONSIDERATE JUDGMENT.

Theories are of human invention, and are but portraits of human limitations and human weaknesses. Facts have a kind of divinity above and beyond the sphere of human agencies. While theories may perish in a day, they alone are unchangeable.

The world is full of theories—while its greatest poverty arises from its need of facts. So great is the want of them, that the bringing to the light of one hitherto undiscovered practical truth renders a life worth living. And all the fine spun theories that have found their expression in successive phases of medical literature have only been

abiding, as they had their foundation in fact.

It is a confession of human weakness, yet not a matter of surprise, that theories have had their birth in every yesterday; their development in every to-day, and their deaths in every to-morrow. The mesian line which segregates the knowable from the vast unknowable which lies beyond is so mysterious and so obscure, that perception, reason and judgment alike confess their weakness and the limitation of their powers. In the study of biology, of physiology, of pathology, and of their modifying environments, the student of medicine often stands as upon enchanted ground. He is painfully conscious that he is within the domain of the knowable; that grand truths are at his finger tips, and he longs to grasp and bring them clearly into light. It is just here that the majesty of great minds is manifest. The power of self-control, to calmly bide the time until beyond question a fact is clearly demonstrated, this is the crowning act of a master mind, the exercise of considerate judgment.

This power of deliberate estimate of evidence more than anything else has been the need of the medical profession in the past, and more than anything else, it is its need to-day. Fancies oftentimes overleap the facts in their haste. Men build their theories upon such foundations, only to wonder that they come to nought so soon.

What the medical profession most needs is the revelation of new facts. What best can serve the world is the revelation of such facts, and there are no such benefactors as those who are giving themselves to original research and the discovering of new truths. We have had our fill of finely devised theories. The present and the future demand is and will be for facts. And we must patiently wait for the demonstration of these facts. We are on the confines of new discoveries as to the agencies of microbes in the production of disease. We have nearly everything yet to learn with reference to their development, their potencies, and the methods of their control.

We are confronted with new questions as to the respiratory powers of the leucocytes and their agencies in the production of animal heat, and with the modifications of their form which govern the activities of their oxidizing powers. We may thus perhaps be led to apprehend more clearly the *modus operandi* of antipyretics in the control of temperatures.

We are yet to learn the connection of electricity with the trophic activities of the tissues, and by what means false growths are retarded, and even obliterated.

Many such are the questions which invite—nay, which challenge investigation, and with reference to which, while we wait in eager expectancy, we can by no means afford to form *prematuring opinions*. We must bide the needed time for actual demonstrations, that our conclusions may be of permanence and value. In nothing more do we need considerate judgment than in our estimates of remedial agents. Here fancy and the wildest imaginations run riot. Not a theory of cure but has its devotees; not a remedy or a nostrum but has its unqualified certificates of cure.

Men with reason and men less gifted alike contribute exaggerated expressions of their faith in all sorts of treatments and of remedies. If ever there was need of the culture of considerate judgment it is here.

And just now, we commend this need to those who are canvassing the merits of Brown-Séquard's Elixir of Life. Let a calm and dispassionate consideration of facts on the part of those who propose to give this article serious attention precede the formation and expression of definite judgments. And we forewarn those who propose to make practical demonstration of its virtues to exercise at least the caution that Hammond enjoins, lest septicaemia and embolism and death follow speedily in the footsteps of reckless experimentation.

#### EDITORIAL NOTES.

##### HOME.

**THE LICENSE ACT IN NEW HAMPSHIRE.**—The law recently passed by the Legislature of New Hampshire for the regulation of medical practice, has had but a short life. A decision has been rendered, by a full bench of the Supreme Court, that it is unconstitutional to require a license as a prerequisite for medical practice. The medical registration act of Maine had a shorter life, even, than that of New Hampshire; since the signature of the Governor was hardly dry upon the bill before that official changed his mind and drew his pen through his name. The President of the State Medical Society, Dr. Stephen H. Weeks, of Portland, took the ground that the bill having once been signed, the subsequent erasure of his

name by the Governor was null and void, and a suit at law has been going on for a year or more to determine which should hold good, the signature or the erasure. The decision has just been reached, in the Supreme Court, and this is adverse to Dr. Weeks and his contention on behalf of the bill. The importance of the registration act to the profession in that State is so great that an effort to pass a like bill *de novo* will be made by the State Society, when the Legislature next convenes.

**EXAMINING BOARD FOR TENNESSEE.**—Under the law recently enacted in Tennessee, the Governor has appointed the following to serve as a Board of Medical Examiners: Drs. James B. Murfree of Murfreesboro, T. J. Happel of Trenton, E. E. Hunter of Elizabethtown and Heber Jones of Memphis, all members of the State Medical Society; also W. B. Halbert, eclectic, and T. H. Hicks, homœopathist. Under the terms of the act, not more than four of the six examiners may be representatives of the same "school of practice." The Board has met and organized by the election of Dr. Murfree to serve as President, and Dr. Happel as Secretary and Treasurer. Dr. Happel is the retiring President of the State Medical Society.

**THE PERIL OF A PHYSIOLOGIST.**—Dr. Weir Mitchell has recently given in *The Century* a decidedly unpleasant experience which befell him while pursuing his investigations concerning the poisons of serpents, especially of the rattlesnake. The snake generally aims his stroke with his poison-fangs with accuracy, but he may make a failure. "The serpent sometimes misjudges distance and falls short, and may squirt the venom four or five feet in the air, doing no harm. I had a curious experience of this kind, in which a snake eight feet long threw a teaspoonful or more of poison athwart my forehead. It missed my eyes by an inch or two. I have had many near escapes, but this was the grimmest of all. An inch lower would have cost me my sight and probably my life." And yet with all his wierd experiences Dr. Mitchell confesses to a certain degree of fascination for the horrid crotalus, and he actually speaks in a tone of regret of the rapidly approaching extermination of the reptile in this country. Dr. Mitchell further states that by the use of the "serpent-staff," a contrivance

which jugulates the snake close to the head, the dangers of laboratory work have been reduced to a minimum, and the physiologist has no need to bring his forehead into direct range with the thrust of the rattler's fangs.

DR. OSCAR J. COSKERY, a member of the Association since 1885, has died at Baltimore in his forty-seventh year. He was graduated from the University of Maryland in 1865 and immediately joined the volunteer staff of the State forces as assistant surgeon. He was not yet 30 years of age when he was elected to the Chair of Surgery at the College of Physicians and Surgeons, Baltimore. He was a prominent contributor to the transactions of the Medical and Chirurgical Faculty of his State, generally in regard to some question of surgery or of hospital organization. He was for many years attending physician to St. Joseph's Hospital. His death occurred on July 5th, from general tuberculosis. He was a man of more than ordinary ability and of high aims, and when we consider his relative youth he had accomplished much.

CONSTITUTIONAL LAW.—The *Legal Adviser* says: A State statute which requires every physician to procure a certificate from the State Board of Health that he is a graduate of a reputable medical school, or has practiced in the State ten years, or had passed a satisfactory examination as to his qualifications, and which makes the practice of medicine without such certificate a misdemeanor, is a constitutional regulation, and does not deprive a physician who has practiced in the State for six years before the passage of the Act of his liberty or property, without due process of law. There is no such "vested right" or "estate" in a profession that the State can not at any time impose upon its exercise such reasonable and appropriate qualifications as are demanded by the public welfare. *Dent v. West Virginia*, 9 Sup. Ct. Rep. 231. (The court distinguish *Cummings v. Missouri*, 3 Wall. 277, and *ex parte Garland*, 1b. 333, as being cases in which the alleged qualifications were, in reality, penalties imposed for past acts, and not reasonable qualifications imposed upon the exercise of professional callings. These decisions, it is said, merely decide that preachers and lawyers "can not be deprived of the right to continue in the exercise of their respective professions by the exaction from them of an oath as to their past conduct respecting matters which have no connection with such profession").

## FOREIGN.

A BENEVOLENT EMPRESS.—The Empress of Japan takes a great interest in the welfare of her suffering subjects. In a year she has contributed \$7,500 out of her "pin money" to assist the Tokio Female Hospital in its good work.

THE PLAGUE IN ARABIA.—The south-west coast of Arabia, bordering on the Red Sea, is again the situation of a reported recurrence of the plague. The *Lancet* of July 20, states that active sanitary measures will be enforced to prevent the spread of the disease. The dates of former visitations of the plague, at this locality, were 1853, 1874 and 1879.

IN FRANCE an association "for the protection of the interests of the medical press," has recently been founded in Paris. The Chamber of Deputies, on a proposition made by Dr. Javal, have decided to exempt the fathers and mothers of seven children from personal or house taxes.

IN GERMANY five years is to be the obligatory period of medical study, including the term of military service. Prof. Engler, of Breslau, has been appointed to the chair of Botany in Berlin University. Dr. von Gossler, Prussian Minister of religion, education and medicine, desires to revive the study of the history of medicine in the Prussian Universities. Dr. Stahl, Professor of Botany at Jena, will leave for Java in October, to make botanical researches there.

IN GREAT BRITAIN, Prof. Robert Bentley, the venerable and able instructor in botany and materia medica has withdrawn from active labors. The British Pharmaceutical Conference meets at Newcastle-on-Tyne, on September 9. The Royal College of Physicians will coöperate with the Father Damien Memorial Committee. Surgeon-General Galbraith died at Cairo on the 31st ult. The Milroy Lectures on State Medicine will be delivered next year by Dr. Ransome, of Manchester, the Goulstonean Lectures by Dr. G. N. Pitt, the Lumleian Lectures by Dr. Hughlings Jackson. The Croonian Lectures for 1890, will be given by Dr. Ferrier; those for 1891, by Prof. Burdon Sanderson. Dr. Macon, Master of the Rotunda Hospital, has been elected King's Professor of Midwifery in the University of Dublin. The medical schools of Dublin are about to amalgamate.

## TOPICS OF THE WEEK.

## THE FUNCTIONS OF PROTOPLASM.

The Croonian Lectures delivered during the present year by T. Lauder Brunton, M.D., before the Royal College of Physicians of London, are so eminently suggestive, and so replete with instruction, that they commend themselves not only to the reading, but to an exhaustive study, by all those who seek by means of physiological research explanation of the specific actions of remedies.

We quote from his third lecture, contained in the *British Medical Journal*, his observations, with reference to cell movement, cell respiration, and its relations to temperatures :

1. MOVEMENTS OF CELLS.—On observing isolated cells, such as the leucocytes of the blood, we can see that they are endowed with life, and will continue to move about on the stage of the microscope as independent organisms for a considerable time after the death of the animal from which they have been taken. Their movements are of two kinds, viz., one of simple contraction or extension of the protoplasm in various directions, while the cell remains in its place, and secondly, movements from place to place. I call your attention specially to those kinds of movement because both are probably of practical importance. The movements from place to place enable the leucocytes, as was first observed by Addison and then by Waller, to move out of the blood-vessels. The importance of this diapedesis, and of the further movements of the leucocyte amongst the cells of the tissues has been clearly demonstrated by Cohnheim and his followers ; but it seems probable that movement of the protoplasm in a cell while it remains *in situ* may be no less important.

2. RESPIRATION IN CELLS.—Kühne showed that isolated cells have the power of absorbing oxygen, by placing them under the microscope in water containing a little oxy-hæmoglobin. After a while they absorbed the oxygen from the hæmoglobin and reduced it. This reduction was discovered by looking at the solution with the microspectroscope, and noticing that it gave the band of reduced hæmoglobin instead of oxy-hæmoglobin as at first. The experiments of Ludwig and his scholars upon circulation through single organs or parts of the body isolated from the rest, and also those of Pflüger and his school upon the gases of the blood, have shown that oxidation and reduction occur in the tissues, but that the amount of each is not always the same, oxidation being sometimes predominant, and, at other times, reduction. Similar results have been obtained in living men by Pettenkofer and Voit. It was found by Harley that the absorption of oxygen and the elimination of carbonic acid by blood could be altered by admixture with various poisons. The power of quinine to lessen such processes was not only discovered by Binz, but brought by him into close relationship with the antipyretic power of the drug, and his researches formed a starting point for numerous investigations into the action of antipyretics generally.

In the admirable lectures which he gave before this

college last year, Dr. MacAlister gave such a complete account of the pathology of fever that I need not do more here than just recapitulate one or two of his chief conclusions.

Increased temperature may depend upon (a) lessened loss of heat by radiation or conduction, or (b) increased formation of heat by greater oxidation in the tissues, and especially in the glands and muscles. The oxidation by which heat is formed in these tissues is regulated by two or three nerve centres within the cranium. Antipyretics, he informed us, appear to lessen oxidation within the body and diminish the formation of heat by stimulating these centres, but he did not discuss the mode in which stimulation of the thermal centres alters the processes of respiration in the tissues, and thus lessens oxidation. This point of the question I propose to take up now, but before I can deal with the action of drugs as antipyretics I must ask your attention for a short time to some observations which have been made upon the respiratory functions of the cell.

3. OXIDATION AND REDUCTION.—From such experiments as those I have already mentioned, it has been known for some time that cells possess the power of taking oxygen from the air, from liquids containing it in solution, or from substances like hæmoglobin, which contain it in a loose state of combination. To this power of removing oxygen from other things the term "reducing" is given, while that of "oxidizing" is applied to the power of giving off oxygen to other substances.

*Double Action of Hæmoglobin.*—Some bodies, like hæmoglobin, possess both powers to a large extent. A solution of hæmoglobin mixed with air absorbs the oxygen from it, and thus has a reducing action, but if this oxidized hæmoglobin be then mixed with some ferrous sulphate it gives up the oxygen to it, oxidizes it, and forms ferric sulphate. It thus loses its oxygen and becomes reduced, the ferrous sulphate having acted upon it as a reducing agent.

*Comparative Degrees of Affinity for Oxygen.*—Substances differ in the degree of affinity which they have for oxygen, it being greater in some and less in others. Thus it happens that we might draw up a scale containing a number of bodies each of which would have a greater affinity for oxygen than the one above and less than the one below it. Each one would therefore abstract oxygen from the one above it, and act as a reducing agent towards it, while it would give up oxygen to the one below it, and thus act as an oxidizing agent.—*British Medical Journal*, June 29, 1889.

## ANTISEPTIC MIDWIFERY.

In the August number of the *American Journal of Medical Sciences*, DR. HENRY J. GARRIGUES, of the New York Maternity Hospital makes special reference to the use of corrosive sublimate and creolin in obstetrical practice.

As the result of extended research he is able to cite twenty-two cases in which the use of corrosive sublimate has been attended with fatal results. In the majority of these cases he is confident that a too strong solution was used. He recommends that the solution be made 1:5000

as yielding the necessary antiseptic action, and less dangerous to the patient.

He speaks secondly of creolin as one of the latest antiseptics, and highly recommends it for thorough trial. It is obtained from English coal, and has the color, consistency and smell of coal tar, and up to 12 per cent. it forms an emulsion with water.

It is rated as second only to bichloride of mercury in antiseptic value, a 3 per cent. solution being fatal to germs in one minute. A 3 per cent. solution causes no unpleasant sensation upon the skin, but a 5 per cent. emulsion causes a feeling of smarting. Solutions of  $\frac{1}{2}$  to 2 per cent. are well borne upon mucous surfaces. Applied in this strength to indolent ulcers it cleanses the wounds, stimulates granulation and healing, often when all other substances had failed. It leaves the surface to which it is applied soft and pliable; and a point of special importance in its use lies in the fact that it is nearly if not entirely innocuous. The following are his conclusions as to the use of these two articles:

1. The solution of bichloride of mercury used for vaginal and intra-uterine injections ought not to be stronger than 1:5000.
2. No more than 1½ quarts should be used.
3. The fluid should be removed from the uterus and the vagina.
4. No injections should be used in normal cases after the birth of the child.
5. Intra-uterine injections should not be given oftener than once or twice in twenty-four hours, vaginal every three hours.
6. The symptoms and signs of absorption should be constantly looked for and the use of bichloride discontinued at their first appearance.
7. The symptoms and signs of abortion should be carefully looked for and the use of bichloride discontinued at their first appearance.
8. It is safest to abstain from the mercurial injections altogether until experience shows that the corrosive sublimate gives better results than any other antiseptic.
9. Corrosive sublimate should be used for disinfection of the outer surfaces of the patient, for the hands of doctors and nurses and for materials brought in contact with the patient.
10. Carbolic acid is perhaps as dangerous an injection as corrosive sublimate.
11. Other less effective germicides may occasionally answer a good purpose.
12. Creolin is an excellent antiseptic; little poisonous, a powerful hemostatic, and makes all surfaces slippery—properties that recommend it especially in obstetrical practice.

#### ACUTE ARTICULAR RHEUMATISM.

In the treatment of this disease DR. H. LINDERBORN thinks that sodium diosalicylate No. II is destined to supplant the use of salicylate of soda. "The dithiosalicylic acids Nos. I and II are two isomeric bodies, each of which consists of two molecules of salicylic acid linked together by two molecules of sulphur. No. II (sodium salt) is a greyish-white powder, very hygroscopic, and easily soluble

without residue in water. According to Hüppe, a 20 per cent. solution kills anthrax bacilli in forty-five minutes, in which time the ordinary salicylate has no perceptible effect; similarly with other bacteria. Four cases of polyarticular and one of the monoarticular rheumatism were treated, also one of gonitis gonorrhica complicated with iridochoroiditis; the dose was 0.2 gram (3 grains) morning and evening—oftener in the more severe cases. The slighter cases showed disappearance of joint-swelling, pain, and fever in two days, the more severe cases in six days. One case was a relapse after salicylate treatment; nausea and noises in the ears were complained of, severe sweating occurred only when 0.8 gram (12 grains) were taken *pro die*. The last mentioned of the above cases was from another hospital, and the patient left cured in ten days. The advantages of this drug over salicylate acid are: stronger action, therefore smaller doses; tolerance by the stomach (the insoluble dithiosalicylic acid is precipitated from the sodium salt in an acid solution); and absence of unpleasant after-effects.—*British Medical Journal*.

#### GASTRIC MUCOUS MEMBRANE.

The power of reproduction with which the mucous membrane of the stomach is endowed seems wellnigh incredible. PROF. L. GRIFFINI and DR. G. VASALLE, after a series of experiments upon fifteen dogs, formulated the following conclusions:

1. The mucous membrane of the fundus of the stomach, removed in dogs, for a considerable extent and in its entire thickness is always reproduced, including the peptic glands.
2. The newly formed glands are developed from the new epithelial layer which in the beginning covers the wound. This epithelial layer itself is developed from the epithelium of the glands on the borders of the wound, thus demonstrating the possibility of the development of an epithelial layer in its totality from true glandular epithelium.
3. The pepsin cells of the newly formed tubular glands are developed in the beginning through a differentiation of the cells of the tubular glands themselves, and this formation originates in the bottom of the tubules, whence the cells are pushed upward.
4. The reproduction process of the peptic glands finds its exact prototype in the process of embryonic development.
5. The reproduction was quite rapid in all the animals, which were strong and healthy and placed amid favorable surroundings. In one case the development was tardy, owing to a considerable loss of tissue (6 cm. equals 2.36 in.) and an unsuitable diet.
6. Perforation of the wall of the stomach never followed removal of the mucous membrane, even though the muscular tunic had been seriously injured.—*Deutsch. Med. Zeitung*, May 9, 1889; *The Medical Bulletin*.

#### RENAL DIURETICS.

Dr. Germain Sée is studying another group of diuretics, which he calls "renal diuretics." They consist of caffeine and theobromine.

## SOCIETY PROCEEDINGS.

## New York Academy of Medicine.

## SECTION ON ORTHOPEDIC SURGERY.

*Stated Meeting, March 15, 1889.*

A. B. JUDSON, M.D., IN THE CHAIR.

## CICATRICAL CONTRACTION OF FINGERS.

DR. A. M. PHELPS presented a patient on whom he had operated four weeks ago for restoration of motion to the fingers, which had been flexed in the palm by a cicatrix in the wrist of eight years standing. He had freed each tendon from the cicatricial tissue, and had secured healing by blood-clot, with the hope that new sheaths would be formed in the clot. The wound was dressed antiseptically, and the first dressing was changed at the end of three weeks. The prospect of recovery of motion was good.

DR. R. H. SAYRE said that Paget had long ago recognized the organization of blood-clot after subcutaneous tenotomy. The case presented by Dr. Phelps shows that advantage can be taken of it after open incision under antiseptics.

## HYSTERICAL EQUINO-VARUS.

DR. N. M. SHAFFER presented a patient, a girl of 12 years, who had been affected for ten weeks with hysterical equino-varus and rhythmical movement of the left foot. The talipes was reduced manually, but the motions were persistent. There was inability to walk, the result of the disability of the quadriceps extensor group. Before coming under Dr. Shaffer's observation, plaster-of-Paris had been applied to the limb for several weeks, but without benefit.

DR. A. B. JUDSON thought that choreic elements were seen when the patient attempted to walk. He recalled a case of rhythmical myoclonus reported by Dr. Peckham in the *Archives of Medicine*, in 1883, in which the patient had been subjected to a great variety of treatment, and finally recovered after the hypodermic use of atropin.

DR. S. KETCH suggested treatment by hypnotism.

DR. R. H. SAYRE thought that the case illustrated the fact that abnormal muscular contraction can produce degrees of deformity as marked as those caused by bony distortion.

DR. L. W. HUBBARD thought the case allied to chorea, being the result of nerve irritation or exhaustion. He suggested absolute rest or recumbency for a long period, with efforts to improve the nutrition.

DR. A. S. HUNTER had treated with success a case of hysterical hip by the administration of ignatia amara. The use of this drug in a number of cases of this kind had led him to value it

highly when the disturbance was limited to groups of muscles only: but he thought it was of little value in the treatment of general choreic conditions.

DR. V. P. GIBNEY had had a favorable effect in a case of rotary spasm of the neck, from the fluid extract of gelsemium, given in five minim doses, and pushed almost to toxic effects.

DR. H. W. BERG said that the contractions in the case shown could not be due to nerve lesion, because it yielded so readily to manual replacement. Where there is irritation of motor nerves, as in spastic paralysis, it is extremely difficult to reduce the limb to a proper position. He suggested the ordinary treatment of chorea with electricity to make an impression on the mind rather than on the nerves.

The paper of the evening was read by DR. PHELPS, entitled

## THE MANAGEMENT OF HIP-JOINT DISEASE FROM AN ANATOMICAL BASIS.

In regard to the pathology of hip disease, Dr. Phelps believes that it is a local tuberculous affection, due to accidental inoculation and not to a constitutional or strumous condition. Following Volkmann, Albert, and König, he believes that the inflammation, at first simple, becomes tubercular by inoculation, and then purulent. The irritation of the peripheral extremities of the nerves in or about the joint produces muscular spasm, which in turn distorts the joint by trauma, aided by the bacilli of tuberculosis.

In regard to treatment, he relies on mechanical treatment, believing that if we immobilize a joint and remove the intra-articular pressure, Nature will take care of the tuberculous material. His experiments on dogs had convinced him that immobilization of healthy joints does not produce ankylosis. Encouraging motion in an inflamed joint is a violation of the surgical law that an inflamed part requires rest. He believes that the muscular spasm, which is a most serious element of destruction, should be overcome by extension, and that while extension is necessary to secure immobilization, it is not sufficient of itself. He therefore resorts to a combination of extension and fixation: the extension always to be in a line corresponding to the axis of the neck of the femur.

Treatment, as a rule, should be begun in bed, extension being made in two directions, *i. e.*, toward the foot-board and laterally, the body and well leg being fixed to a long splint extending to the axilla. If the deformity does not yield to extension properly applied, the tissues at fault should be divided subcutaneously, or by open incision. Abscesses are to be incised through their entire length, and thoroughly scooped out and washed, strict antiseptic precautions being observed. Distension of the capsule should be re-

lieved by aspiration or incision; then traction will not produce pain.

He exhibited a patient in a portable bed, which is an ingenious substitute for the wire cuirass, made with a board cut in an outline of the body, and plaster-of-Paris. The child is laid on the board, and then the whole enveloped with plaster-of-Paris bandages from the foot to the axilla. The plaster is then cut away in front, the interior comfortably padded, and the patient held in place by lacings or bandages. Extension and fixation in bed are to be continued until the active symptoms and the deformity have entirely disappeared, and the spasm of the muscles is no longer present. Adults are then given crutches, and a portable splint which has a perineal crutch, extension by adhesive plaster, an abduction bar, and an upper (thoracic) ring to prevent flexion and extension at the hip. Children, after treatment in bed, are to have the portable bed, and then the portable splint, with or without the high shoe and crutches.

DR. J. RIDLON was much pleased to hear the author of the paper take the ground that hip cases should be cured without deformity. He recalled a case of a patient in which the muscular spasm had been relieved by pinching the muscle. The child was very thin, and it was found that when the adductors were separated from the other muscles, and the belly of the muscle was pinched without any attempt at fixation, there was as much relief as could have been afforded by lateral traction.

DR. SHAFFER said that the paper had suggested to him the importance of separating in our minds the disease from the deformity. It is a question how far we are justified in meddling with the deformity, which is simply an expression, or so to speak, a symptom of the disease. In his experience, attempts at speedy reduction of the deformity had been followed by disastrous results. Nature gives a very positive indication in the acquired position of the thigh—that in which the immobilization of Nature reaches its maximum, and the diseased parts receive the greatest relief from reflex muscular spasm. If we forcibly interfere with this effort on the part of Nature, we inflict a distinct traumatism.

On the threshold of treatment, the important question is, not whether traction is to be made in the line of the shaft or the neck, but how to secure an artificial immobilization in the position nature assumes as the one that affords the most protection to the inflamed parts. He believed that if the joints were protected from traumatism, in other words, if traumatic contact of the inflamed joint surfaces is removed, and this can readily be done by the use of portative apparatus without entailing immobilization of the entire body from the head down, the joint is placed in the best known local condition.

The portative traction treatment is compatible with fresh air, sunlight, and moderate exercise, which are the best means of combating the tubercular disease, and the tubercular diathesis. More lives have been saved, and better results have been thus secured, than by any other method which has been thoroughly tested.

DR. R. H. SAYRE agreed with Dr. Shaffer as to the importance of maintaining the general health, and the inadvisability of general immobilization of the body, if the diseased joint could be controlled without it. He thought that complete immobilization of the hip-joint in young children was very difficult to secure; and that the movement that stopped short of producing muscular spasm and pain, was not harmful. For poor children particularly, he thought the portable bed was an admirable contrivance.

The relief obtained in some cases by pinching the muscle could be explained on the supposition that it stopped the reflex action of the muscle. It is known that firm constriction of the belly of a muscle will, in certain cases, abolish spasm.

DR. CHAS. L. SCUDDER, of Boston, advocated a more frequent resort to the results of experiment on the cadaver. He recalled Dr. Bradford's experiments made in 1880, in which it was found that in an adult a force of one hundred pounds was not sufficient to separate the head of the femur from the socket; while in the shallow and not yet completely ossified acetabulum of a young child, a moderate force caused separation, and still less force was required in the fetus. Dr. Scudder believed that in hip disease of children, a tractive force of from three to five pounds would separate the joint surfaces as was illustrated at the Children's Hospital in Boston, in the case of a young boy who had hip disease and night cries. The joint cavity was opened and a small quantity of pus evacuated. While the boy was under ether, it was found that traction made with the hand separated the joint surfaces to such an extent that the finger could be placed between the head and the acetabulum.

DR. HUBBARD thought that no one at the present time held the opinion that ankylosis is caused by immobilizing the joint affected with chronic inflammation. He had found it difficult to get ankylosis in cases where it was desirable, as in disease of the knee. The first object is to give rest to joint, which is best done by traction; not to separate the surfaces, but to overcome articular pressure which leads to muscular spasm. He believed the long hip splint gave sufficient immobilization for all practical purposes. It is more easily managed than the portable bed of Dr. Phelps, which from neglect would be likely to cause excoriations. As the disease seems to be a struggle between the tubercle bacilli and the vitality of the organism, he thought it especially important to place the system in the best possible

condition to resist attack. He had rarely seen constitutional disturbance from abscesses which had been let alone, although in exceptional cases acute and painful conditions are certainly greatly relieved by surgical interference.

DR. JUDSON commended the title of the paper. It was an admission that hip disease is not to be cured by treatment, but so managed that the almost inevitable recovery by natural processes should be with the minimum of disability and deformity. He thought that more emphasis should be placed on the importance of protecting the joint from the traumatism of standing and walking, as is done by the use of Hutchison's extra long crutches and high sole on the well foot. But in every case there are long periods of exemption from pain, when this simple apparatus will be discarded. The ischiatic or perineal crutch of the hip splint, however, cannot be willfully discarded; and when it is seen that the rack and pinion not only furnish traction, but also a convenient means of adjusting the length of the upright, the hip-splint appears to come very near perfection as an instrument for the management of hip disease. He had never recognized either the trauma said to be caused by reflex muscular contraction or the alleged mechanical counter-action of the muscle by traction. He believed, and had always held, that the hip-splint mitigates reflex muscular contraction by allaying the inflammation which gives rise to it. This it does by arrest of motion and prevention of pressure; motion being arrested by traction brought about by the use of the key, and pressure being averted by the perineal or ischiatic crutch, which makes the limb a pendent member. As the inflammation is resolved the reflex muscular contraction ceases.

The last annual report of one of our orthopaedic institutions contains a table, from which it appears that there have been under treatment 371 cases of disease in the hip; 6 in the shoulder; 85 in the knee; 3 in the elbow; 27 in the ankle; and 5 in the wrist; an aggregate of 483 in the lower, and 14 in the upper extremity. Shall we draw the inference that the incipient osteitic focus is found only or chiefly in the cancellous tissue of the lower extremity, or that a focus in the upper extremity more readily undergoes resolution by reason of its comparative exemption from violence? If the latter view is correct, it follows that the limb is to be made a pendent member by the persistent use of the axillary or ischiatic crutch at the earliest recognition of the disease. In some cases, an earlier diagnosis may be facilitated by the following simple method:

Let the patient sit on a table with the legs hanging and the knees separated; in this position, swinging the leg laterally is possible only with rotation of the femur; and if one leg oscillates in a less arc than the other, it induces or con-

firms a suspicion of the integrity of the joint. He did not believe in treating abscesses and sinuses excepting indirectly through the general and local management of the bone disease in which they have their origin.

DR. GIBNEY was in favor of securing absolute immobilization, but sometimes he would rather have less perfect immobilization, if by so doing he could secure a change of air and climate, with the consequent improvement in the general nutrition.

Ordinary hip disease is managed satisfactorily by the portable traction splint, with or without the rack and pinion; and he had been agreeably surprised with the facility with which these patients ran around in the tenement houses. They come to his clinic only every three or four weeks for adjustment of the apparatus; and, during these intervals engage in the most active sports; they certainly do not lie in bed in dark rooms and die of pyæmia. It is unsafe to put these children in an appliance like a cuirass or the portable bed, unless one is certain of being able to see and attend to them at short intervals. It had been his lot to see cases in which he had been unable at times to obtain proper co-operation on the part of the patient's family. He had often seen abscesses burrowing up to the spinal column and down to the knee; and such cases seemed to baffle even attempts at surgical interference. We must be guided a good deal by circumstances, and if we can protect the hips from trauma and give the patient the benefit of outdoor exercise, abscesses will generally be insignificant.

He believed in correcting the deformity speedily, if necessary by dividing tendons and bone under an anæsthetic; for by so doing, we save much time and lose nothing. In regard to aspirating the joint over-distended with fluid, it was almost impossible to diagnose an over-distended hip-joint. The position of the limb does not depend on the quantity of fluid in the joint, but is due to reflex spasm, and the efforts made by the child and nature to secure fixation.

DR. J. H. GIRDNER described an experiment on the cadaver in which great force was applied without separating the surfaces of the hip-joint. He also cited a case in which it had been necessary to keep the hand applied to the face for nine weeks in the course of a plastic operation on the nose. At the end of this time, there was no limitation in the motions of the elbow and wrist.

DR. KETCH believed that hip disease is so often characterized by exacerbations that all attempts at a division into stages are of no practical value. He thought that the hip-splint could be often of use for the reduction of deformities even in those periods when the patient is confined to his bed. In general, he believed it was a great mistake to make use of any apparatus which can

be entirely left to the care of the patient or family for long periods. The explanation of the relief of pain by compression of muscles was to be found in an involuntary action on the part of the patient which secures fixation and traction at the same time.

DR. BERG, speaking from the standpoint of the general practitioner, who frequently saw children in the very beginning of hip disease, related the histories of three cases which had presented the symptoms of early hip-joint disease, and yet recovered perfectly after rest in bed for a few weeks. He now insisted on all such patients remaining in bed for several weeks before commencing any other treatment.

DR. PHELPS, in closing the discussion, said that many cases in tenement houses, whether treated by the long traction splint or by the portable bed, are deplorably neglected; but this does not argue against the use of either apparatus; it simply illustrated one of the difficulties with which all practitioners have to contend. He valued the portable bed because he desired immobilization of the affected joint, and this could not be obtained with splints having joints in them, and not including the trunk. He could relieve his patients better in bed during the period of deformity, and so adopted this method of treatment. He had seen patients in England who had been in bed for several years, and were still in excellent health. He did not, however, advocate prolonged bed treatment. Believing that the cases in question are inoculations of the bacillus tuberculosis on a previously inflamed surface, and not instances of constitutional tuberculosis, he explained the frequency of tubercular joint diseases in the lower extremity, by the statement that the joints of the lower extremities being more subjected to traumatic inflammation, furnish good ground in which the bacillus of tuberculosis could more readily reproduce itself. He had presented his honest convictions, and hoped to report his cases later in such a way that others could disprove his statements, or he could substantiate his views.

orable journey from the Congo to Lake Nyanza. Hitherto it has been asserted, with very little evidence in many cases, that all the arrow poisons of savages have been extracted from vegetable substances. But according to Mr. Stanley's recent experience ants are the source of the poison. Five members of the expedition were hit by these weapons and four black men died very shortly afterwards, their sufferings having been intense. The fifth man hit was a white man, and he had a very narrow escape. The poison of the arrow which hit him had become dry and so he did not experience its full effects. It was afterwards found that the poison is manufactured from the dried bodies of red ants, which are ground to powder, cooked in palm oil, and smeared over the wooden points of the arrows. Some think that this poison must consist of formic acid. Others argue that some kind of ptomaine or animal alkaloid is thus obtained from the dead ants; but as these insects are dried and pulverized and afterwards cooked in oil, it is difficult to see how any ptomaine could be formed, for these animal alkaloids are the product of putrefaction, and it is not stated that the ants are allowed to putrefy. Hence it is not improbable, as *The Lancet* was the first to suggest, that the terrible poison of these arrows is formic acid or some organic derivative of that acid, more or less allied to prussic acid.

The petition for an inquiry into the management and organization of metropolitan hospitals has been energetically taken up by a very large number of leading physicians and surgeons and others who have special means of understanding what is wanted. More than 450 medical men have signed the petition, the great majority of whom are professors, lecturers, physicians and surgeons actually connected with hospital work. There is really most excellent reason to believe that if our London hospitals and dispensaries were only organized properly there would be no need for the constant appeals for public aid in the form of hospital shows, bazaars and other wasteful means of raising funds. The petition draws special attention to the glaring defects in our present lack of system. Out-patient departments are generally gorged with a crowd of people suffering from trivial complaints. Many of the applicants belong to classes for which charity is quite unnecessary. Another great administrative flaw is the total absence of any clear and definite division of labor between voluntary hospitals and dispensaries and those provided under the Poor Law. A scheme might be devised which would create special relations between neighboring hospitals and dispensaries, grouping them together, and providing means for the transference of cases from one to the other. But supposing these points to be satisfactorily settled, there will still remain the most difficult and delicate task of all in dealing with the sporadic establishment of unnecessary

## FOREIGN CORRESPONDENCE.

### LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

*The Nature of Arrow Poison—The Proposed Inquiry into the Management of Metropolitan Hospitals—The Action of Antipyrin—Tubercular Abscess of the Breast—The Aversion of some Animals to Saccharin—Miscellaneous Items.*

Some of our medical journals are discussing the nature of the arrow poison which proved fatal to several of H. Stanley's followers during their mem-

hospitals. It is absurd to allow the waste of money which takes place every year by the foundation of new special hospitals almost under the shadow of great institutions in which whole wards are lying idle for want of funds. None of these difficulties are easy to deal with, and there can be no doubt that a well chosen select committee will be able to clear up much that is obscure and suggest the outline of a better order of things.

Dr. C. R. Illingworth has published the following important suggestion: He says antipyrin has been lauded as a hæmostatic. It is his opinion that as such it acts by preventing the formation of fibrin so thoroughly and effectually that there is less resistance to the flow through capillary blood-vessels in the vicinity than into the atmosphere, and more attraction. This power of antipyrin and its allies, he suggests, should prove serviceable in the treatment of sanguineous apoplexy, reducing the lesion to a minimum, and rendering complete recovery possible in many cases if taken early enough.

An important paper was recently read by Mr. Shattock on "Tubercular Abscess of the Breast." In the course of the paper it was stated that in the cow "tubercle of the udder" was a well known disease, so much so that on the Continent its hygienic importance was generally and practically recognized. Dr. Hamilton, a distinguished Aberdeen professor, has expressed the opinion that tuberculous milk from cows may often be the cause of what is popularly known as "consumption of the bowels." He cites a case of a perfectly healthy child, born of equally healthy parents, which was given to a wet nurse to be suckled. The woman was tubercular and the child very quickly contracted meningitis and died. The nurse's milk, on examination, was found to contain the bacilli of tubercle. Both Mr. Shattock and Dr. Hamilton have been impressing upon the public the necessity for always having milk cooked before it is used. It is suggested that the addition of a little sugar to the milk when boiling gives it quite a new flavor, and makes it more palatable than uncooked milk. For those who do not like what is sweet, a pinch of salt may be put in, and that again produces a substance having a totally different taste from plain boiled milk.

It has been discovered that animals such as dogs and cats have a curious aversion to saccharin. In some experiments recently neither carresses nor threats could induce them to eat bread on which only a very small portion of saccharin had been strewn. Water sweetened with small quantities of saccharin, which was poured down their throats was instantly vomited by them. In another case a very small quantity of saccharin was mixed with the food of three cats which they only received once a day. In each case they left it absolutely untouched. In spite of their being

very hungry, as was quite evident from their cries and movements, they did not meddle with the food during four hours. After this food free from saccharin was placed before them, which they quickly devoured, after they had sniffed it some time. It is considered that these experiments prove saccharin to have a peculiar odor which is easily perceived by the animals mentioned, but does not affect the human being.

The Bradshaw Lecture will be given this year by Dr. Norman Moore, of St. Bartholomew's Hospital. The subject chosen is "The Distribution and Duration of Visceral New Growths."

Surgeon Parry, of the Indian Medical Department, says he saw the jet black hair of a rebel Sepoy turn grey in half an hour, while he was under examination and half mad with fear, and he also relates the case of a gentleman who left home on his wedding tour with dark hair. When he came back a month later his hair, his beard, and even his eyebrows, had become snow-white.

A new clinical thermometer has appeared constructed with a layer of ruby red or other colored glass behind the bore, backed by a layer of opaque enamel. By these simple means the contents of the bore, as well as the divisions on the glass, are more readily made visible.

The work on Diseases of the Lungs, which occupied the late Dr. Wilson Fox during many years, is now in the press and will shortly appear. It presents the thorough method which always characterized the writings of this author. The editor, Dr. Sidney Copeland, was one of Dr. Fox's pupils. It will be in the hands of the public during the autumn.

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*The New Mausoleum Plan for the Disposal of the Dead—Dr. John M. Peacocke and Dr. A. N. Bell discuss the subject—Executions by Electricity—Dr. Wm. A. Hammond and the Brown-Séquard Elixir.*

Of late the new mausoleum plan of disposal of the dead has attracted considerable attention in this city. The project seems likely to meet with much favor both from sanitarians and the public at large, and a company, in which many clergymen and physicians are interested, has now been organized for the purpose of erecting suitable buildings in the leading cities of the country. While the objections to the prevalent mode of disposal of the dead are generally recognized, cremation meets with much opposition, and it is believed that this new sanitary system will be widely adopted as a substitute for burial.

The buildings, each of which will contain from

ten to forty thousand sepulchral spaces, will be constructed, in the most substantial and durable manner, of concrete prepared from the best Portland cement, sand and broken stone. Concrete is the basis, the corner-stone of the new system, and without concrete it would not be practicable. The sepulchral spaces will be constructed with conduits conveying fresh dry air into the casket, whence it is carried by forced drafts to a central furnace in the sub-cellar. To this furnace the gases and vaporized fluids of the body are thus borne, and there consumed; so that the escape into the atmosphere of any noxious matter is perfectly prevented. There are left behind the mineral and solid parts of the body, in a properly dessicated condition, with the form and features intact, and wholly inoffensive to sight or smell. The tissues become cellular and sponge-like as the moisture is extracted, and while the weight of the subject is reduced two-thirds at least, there is no marked emaciation. The process was first thoroughly tested under the observation of the late Dr. A. Y. P. Garnett, of Washington, who declared that the principle of the new mausoleum was one of scientific accuracy reduced to a practical fact. More recently the experiments have been conducted in this city under the supervision of Drs. C. I. Pardee and Rudolph St. Witthaus, of the Medical Department of the University of New York.

The mausoleum buildings will be of handsome architecture, with granite facings, and the roof constructed of glass and iron. The interior plan will resemble that of a well-appointed library, with a main corridor and diverging halls leading to the different sections. The sepulchres of solid concrete, four inches thick, seamless and jointless, will be arranged in tiers of six upon either side of the hallways, and the opening into each will be provided with two doors; the inner one of plate glass, hermetically sealed, and the outer one of metal or stone, decorated according to taste. Family vaults will be arranged in separate compartments of various sizes, and each mausoleum will have a beautiful chapel. There will be no possibility of stealing the dead, and the buildings will be absolutely fire-proof.

In an elaborate paper on "The Disposal of the Dead," read a short time since before the Medical Society of King's County, Dr. John M. Peacocke expressed himself as follows in regard to the proposed new method: "The dessicating process has many commendable features. It complies with all the sanitary requirements, and meets the medico-legal demand that the evidence of crime shall not be destroyed. The rapid abstraction of moisture by this method will do away with the factors in the production of ptomaines which might vitiate the result of a chemico-legal examination. This system is devoid of everything that can shock sensitive minds or offend refined tastes.

It does not conflict with the widespread and deep-seated reverence felt for the remains of the dead. The mass of mankind looks not only with aversion but with feelings akin to horror on any process that aims at immediate destruction of the body. This may be all sentiment, nevertheless no amount of specious reasoning can readily or easily overcome the tender and universal deference for the beloved departed, for it is woven into the very warp and woof of the human heart, and has the religion, the tradition, and the custom of centuries associated with it. . . . It is evident that the introduction of any change in the present method of disposal of the dead will naturally encounter suspicion, criticism and opposition; except in the case of the method of desiccation, which seems to have been received, as far as presented, with marked favor."

In the discussion of the paper Dr. A. N. Bell, editor of *The Sanitarian*, stated that the single sentiment to which he wished to give utterance was, the necessity for so disposing of the dead as not to endanger the life of the living. In the course of his remarks he said: "There is a proposition now on foot to build grand mausoleums in connection with or independent of the cemeteries, as the case may be, where the sentiments of certain people can be gratified, if they do not wish to bury their dead, or are prohibited from, as they certainly should be in many cases, from burying them so as to endanger the living, and are unwilling to have them cremated. I mention this as only one of the means of disposing of the dead without danger to the living, because it overcomes the objection which touches the sentimental emotions of individuals who think cremation lacking in sacredness, and too rapidly destructive. . . . But the new mausoleum process fully meets this sentiment, while it also overcomes the medico-legal objection urged against cremation, and, like it, effectually disposes of the dead without danger to the living."

In the case of the murderer Kemmler, the first criminal condemned to execution by electricity in accordance with the new law relating to capital punishment, the counsel for the prisoner some time since obtained a stay of proceedings. They claimed that the law was unconstitutional, on the ground that death by electricity is a "cruel and unusual" form of punishment, and for more than a month expert testimony has been taken before a referee in regard to the effects of electricity upon the animal economy. There can be little doubt, however, that the chief incentive for the proceedings to test the constitutionality of the law is the objection of the electric light company whose apparatus has been solicited for the execution of criminals to having it employed for this purpose, lest those using it for other purposes should get the impression that the current is dangerous to human life. The matter has in reality resolved

itself into an inquiry whether, upon the whole, the Legislature was justified in passing the law in question; and it is certainly a fact that if this appeal is successful, capital punishment will have been abolished, or at least suspended, in the State of New York, since there is no warrant in the law as it now stands for putting a man to death in pursuance of a judicial process by any other means than the application of electricity.

Still, the testimony obtained as to the efficiency of the alternating electric current for the desired purpose has been so conclusive that it seems altogether probable that this attempt to prevent the execution of the law will fail. Among the witnesses examined was Dr. A. D. Rockwell, the specialist in electro-therapeutics and nervous diseases, who assisted in the experiments made upon animals at the Edison laboratory before the law was passed by the Legislature, and he unhesitatingly testified that, from his knowledge of the subject and the experiments he had witnessed, he believed that an electric current can be artificially generated which will kill a man instantly and painlessly in every case where it is scientifically applied; also that the electrodes can be so placed upon a criminal in the apparatus proposed to be used in electrical executions that there will be no probability of his being burned. He expressed his conviction that an alternating current of 1,000 volts would always destroy life, and in this opinion he was confirmed by Edison, the electrician. In regard to an alternating current of 1,500 volts, such as it is proposed to employ in executions, Dr. Rockwell stated that he had no doubt whatever that it would inevitably kill. Such a current, he said, would of necessity produce a rupture of the muscular tissues and immediately stop the action of the heart; causing a paralysis of the nerve centres.

Mr. Harold P. Brown, the electrical expert who has contracted to furnish to the State the apparatus to be used in executions, has recently arrived at Auburn, where the prisoner Kemmler is confined, and in the presence of Dr. Carlos F. MacDonald, late Superintendent of the State Asylum for Insane Criminals, and others, he will make a series of experiments with the identical apparatus which it is proposed to use in the case of Kemmler. Mr. Brown states that he has a list of no less than ninety individuals who have been killed by contact with electric wires. Twenty-seven of these were killed by the alternating current and fifteen by the Westinghouse dynamo, which is to be used in the execution.

Dr. Wm. A. Hammond, who like most others was at first disposed to pooh-poooh Brown-Séquard's alleged discovery of the rejuvenating power of the testicle, now announces that the results of a number of experiments which he has himself made are such as apparently to confirm the correctness of Brown-Séquard's assertions.

In the experiments he used the testes of freshly killed lambs, in preference to the rabbit or guinea pig, employed in France; great care being taken to thoroughly filter the solution employed in the injections. He began his experiments first on himself, to make sure that the method was not dangerous to the patient. Since then he has experimented on several old men without their being aware of what was being done to them, and in the case of one of them, he states that the result was quite remarkable. He was about 60 years of age and had his arm so nearly paralyzed with rheumatism that for nearly a year he had not been able to raise his hand to his head; while soon after one injection he could move it in any direction and almost as vigorously as he had ever done. Of course, Dr. Hammond does not claim any conclusive results with the limited number of experiments thus far made, but he says he feels justified in proceeding further with the investigation.

#### **Audi Alteram Partem.**

*To the Editor:*—In an editorial in the last issue of *THE JOURNAL* which I have read with a great deal of interest, you attempt to draw a comparison between the results of the medical and the surgical treatment of acute intestinal obstruction, and you claim that whereas 30 per cent. recover after medical treatment, 68.9 per cent. succumb to surgical treatment. If you will permit me to venture an opinion upon this subject, I would suggest that you are not stating the proposition fairly. You no doubt are aware that only those patients are subjected to surgical treatment who, in spite of the old and classical opium treatment, continue to grow worse; and that operative interference is, as a rule, unfortunately delayed till the patient is greatly exhausted and his physician and friends realize that death is inevitable without the same. As in cases of intestinal obstruction, therefore, medical treatment is adopted at the very outset, and surgical treatment only resorted to after medical treatment has failed, a comparison between the results is scarcely feasible. And yet the statistics you adduce prove that, even under prevailing circumstances, the results after surgical treatment are slightly better than those of medical treatment. How much better they will be in future, when we have learned the important lesson that in order to prove successful, grave operations have to be undertaken in "good season," can only be surmised.

I have noticed with a great deal of regret that in recent editorials of *THE JOURNAL* an effort is made to discourage grave operations, particularly in obscure abdominal affections; for every unbiassed physician will readily admit that especially in abdominal affections operative interference has been crowned with marvelous success, and that

thousands of lives are now saved that without such interference would be doomed to an early death. And I am persuaded that even to-day ten lives are lost for the want of timely and early surgical interference to every one sacrificed by an unnecessary and premature operation. Within the last year I have seen two patients with strangulated herniæ die; in both cases the incarcerated intestine had sloughed, and yet the attending physicians seemed to think that they had done their duty to their patients by feeding them on opium and letting them die.

Every practitioner knows how much a patient dreads the knife and how difficult it is, as a rule, to obtain his consent to an operation which really offers the only chance for his recovery. Every one knows, too, how often even physicians discourage operations, even in cases where they are imperatively demanded, for no other reason than that they are not prepared or unable to perform the same.

It would seem that for these reasons it is of questionable prudence for any prominent medical journal to deprecate any operation which already has saved many lives, and which will in the future, as the technique of the same becomes more and more improved, undoubtedly show a still larger percentage of recoveries.

H. H. VINKE, M.D.

St. Charles, Mo., August 16, 1889.

## NECROLOGY.

### Dr. James L. Cabell.

Dr. James L. Cabell, who died at Overton, Va., on the 13th inst., was one of the early members of, and a frequent contributor to the reports of the American Medical Association. He was for more than fifty years identified with the University of Virginia, in its department of medicine. He was an alumnus of that University in 1833, in arts. He obtained his medical degree at the University of Maryland in 1834. He studied abroad and at home, for three years, preparing himself for the professorship at Charlottesville, which came to him in 1837, when he was only 24 years of age. His first chair was that of anatomy and surgery. He continued with the University until the end of the session recently closed, when he retired to make room for his former pupil, Dr. Barringer, his health rendering the step expedient. He was prominent in his State Medical Society, and in the American Public Health Association, becoming the presiding officer of each in 1876 and in 1878, respectively. He was Chairman of the Health Conference at Washington, during the epidemic of yellow fever at Memphis. His eminence in the field of

public hygiene led to his appointment as president of the National Board of Health, a position filled by him for several years with great advantage to the public service and to the cause of sanitary science in this country. He was the recipient of many honors and a member of many important societies, nearly all of which profited, from time to time, by the contributions of his learning and ripe judgment. He was in his seventy-sixth year at the time of his decease.

### Dr. Alexander Mott.

The readers of THE JOURNAL will regret to learn of the death of Dr. Mott, on the 12th of the present month. He died at Yonkers, of pneumonia, after a sickness of two days. Dr. Mott was a well-known member of a well-known family. He was a son of Valentine Mott, the world-renowned surgeon. Alexander Mott was born in New York in 1826. Few surgeons were as well known in New York up to 1860, when he organized the medical corps of the militia work. He was commissioned a surgeon in the U. S. Volunteers in 1862, with the rank of Major. He founded the United States Army General Hospital in New York, and about the end of 1864 he became medical inspector of the department of Virginia, and was attached to General E. O. C. Ord's staff. Dr. Mott was at the memorable conference between General Grant and General Lee when the terms of surrender were arranged, and, with the brevet of Colonel, was mustered out of the service on July 17, 1865. He then resumed practice in New York, and helped to found Bellevue Medical College, where he was Professor of Surgical Anatomy and remained until 1872. He leaves a son, Dr. Valentine Mott, who is also well known in the medical profession.

## MISCELLANY.

**HYGIENE.**—It is the province of hygiene to seek out and determine the causes of disease, and to formulate rules for their prevention and removal. It may thus be called also preventive medicine. The progress of hygiene, such as it was, rested for many ages upon an empirical basis; and indeed, to a large extent, this is still the case. The subject has, however, in later times at least, been studied to considerable advantage, though much remains to be done.

Two centuries ago the mortality of London was 80 per 1,000; at the present day it is under 23. A century ago ships could barely keep the sea for scurvy, while jails and hospitals were in many cases the hotbeds of fatal diseases. Now, these conditions are rectified, or at least the means of rectifying them are known. Thirty years ago the English troops at home died at the rate of 20 per 1,000, now their death-rate is less than one-half of this. A knowledge of the causes and modes of propagation of disease being necessary in order to provide rules for its prevention, it is obvious that hygiene must be largely dependent upon the advances made in pathology and

etiology; hence the impossibility of any yearly marked progress in former times, by reason of the imperfection of the collateral sciences, and the want of the appliances more recently made available for inquiries of such difficult and recondite character.

Within this century, however, and especially within the last forty or fifty years, it has been possible to follow out the subject on a more strictly scientific basis, and so to lay a foundation at last on which to build a structure which may one day entitle hygiene to a place among the more exact sciences.—*Plumber and Gasfitters' Review*.

**NEW YORK STATE MEDICAL ASSOCIATION (FIFTH DISTRICT BRANCH).**—The seventh special meeting of the Fifth District Branch will be held in the Fowler House, Port Jervis, at 2 P.M., on Tuesday, August 27. The following scientific papers will be presented: "Some Observations on the Use of Concentrated Lactic Acid," by W. B. Eager, M.D.; "The Treatment of Typhoid Fever, with special reference to the Cold Water Method," by J. H. Hunt, M.D.; "A Case of Empyema," by H. B. Swartwout, M.D.

For those who may desire to remain over night, a drive to Milford, Pa., to visit the Sawkill Falls (with supper at the Fanchere House) has been arranged for. Friends of the Fellows—both medical and lay—are cordially invited to participate in this excursion. Ladies are especially invited.

The total expenses for the whole trip, which includes the railroad return ticket between New York and Port Jervis, dinner at the Fowler House, drive to Milford and return, supper at Fauchere's and accommodations over night at Port Jervis, will not exceed \$6.50 for each person. If there is a large attendance this amount will be considerably reduced.

**THE LATEST** arrivals of new remedies in this market include wrightine, frequently mentioned in journals of late, condurangin, kawain, from Kava Kava, and pyrotechin, used by photographers.—*Notes on New Remedies*.

**DR. N. SENN** has been proposed for honorary membership in the National Academy of Medicine of Mexico.

**THE UNITED STATES HAY FEVER ASSOCIATION** will hold its sixteenth annual meeting on the 27th inst., at Bethlehem, N. H.

**SULFONAL.**—Dr. T. Lauder Brunton says, in one of the Croonian Lectures, that sulfonal appears to be one of the most effective of all the newly introduced hypnotics, and although it does not, like morphine, compel sleep, it induces sleep in a pleasant manner and has few disagreeable effects and little or no danger. Sulfonal has recently declined in price.

**AN INFANTS' SUMMER HOSPITAL** has been established by the citizens of Rochester, N. Y., at Charlotte, on Lake Ontario. Dr. E. M. Moore is President of the Association, and Dr. George W. Goler is attending physician. Any child suffering from intestinal trouble is treated free of charge. There are accommodations for twenty patients, and many children who would otherwise have received no medical treatment have been cared for.—*N. Y. Medical Journal*

#### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from August 10, 1889, to August 16, 1889.*

Major William H. Gardner, Surgeon U. S. Army, Washington Bks., granted leave of absence for one month. Par. 1, S. O. 183, Hdqrs. Div. of the Atlantic, Governor's Island, New York City, August 13, 1889.

Major Washington Matthews, Surgeon U. S. Army, promoted to Surgeon U. S. Army, with rank of Major, to take effect from the 10th day of July, 1889, vice Tonn, promoted. War Department, Washington, D. C., August 14, 1889.

By direction of the Secretary of War, a board of medical officers, to consist of Lieut.-Col. Anthony Heger, Surgeon, Capt. John O. Skinner and Capt. James C. Merrill, Asst. Surgeons, will assemble at the U. S. Military Academy, West Point, N. Y., on August 25, 1889, or as soon thereafter as practicable, to examine into the physical qualifications of the candidates for admission to the Academy. Par. 9, S. O. 185, A. G. O., August 12, 1889.

By direction of the Secretary of War, Capt. Joseph Y. Porter, Asst. Surgeon, now at Jacksonville, Fla., will, if the state of his health will permit, proceed to Jackson Bks., La., and report to the commanding officer of that post for temporary duty, and by letter to the commanding General, Div. of the Atlantic. Par. 16, S. O. 186, A. G. O., August 13, 1889.

Capt. Valery Havard, Asst. Surgeon U. S. Army, granted leave of absence for one month, to take effect about October 1, 1889, with permission to apply to Division Hdqrs. for an extension of one month. Par. 3, S. O. 80, Dept. Dak., St. Paul, Aug. 10, 1889.

#### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending August 17, 1889.*

Surgeon B. F. Rogers, detached from U. S. S. "Alliance" and wait orders.

Surgeon G. E. H. Harmon, ordered to the U. S. S. "Constellation." August 13, 1889.

Asst. Surgeon C. H. T. Lowndes, ordered to the U. S. S. "Constellation." August 13, 1889.

Asst. Surgeon C. J. Decker, detached from U. S. S. "Lancaster" and granted four months' leave of absence.

P. A. Surgeon L. B. Baldwin, detached from U. S. S. "Ranger," ordered home and wait orders.

Surgeon H. P. Harvey, ordered to the U. S. S. "Ranger." P. A. Surgeon P. A. Lovering, ordered to the receiving ship "Wabash," at Boston Navy Yard.

Surgeon C. A. Siegfried, ordered to the naval station at New London, Conn.

## ORIGINAL ARTICLES.

### ABSTRACT OF A PAPER ON THE CHOICE OF TREATMENT OF URINARY CONCRETIONS.

*Read in the Section of Surgery and Anatomy at the Fortieth Annual Meeting of the American Medical Association, held at Newport, June 25, 1889.*

BY JOHN W. S. GOULEY, M.D.,  
SURGEON TO BELLEVUE HOSPITAL.

In the examination of the several modes of treating urinary concretions, the question of their indications and contraindications is worthy of special attention, since adherence to a single procedure belongs to the medicine of a remote past. Modern medicine demands that preventive measures be taken in threatened calculous affection at the first sign of coming of hyperlithæmia; that when hyperlithuria exists, medicinal treatment be resorted to; that when calculi are formed, mechanical means be promptly applied for their removal; that when the calculi have been removed, the cure be accomplished by suitable after-treatment; and that when mechanical treatment is contraindicated, a judicious course of palliative treatment be adopted. Therefore the treatment of urinary concretions is now arranged into the preventive, medicinal, palliative, mechanical and post-mechanical treatment.

*The preventive treatment* embraces hygienic, medicinal and mechanical means. The needed hygienic observances comprise diet, exercise, abluitions and raiment. The medicinal means of prevention are directed against dyspepsia and intestinal and hepatic inaction. The mechanical means of prevention are applicable to cases of bladder injuries, of foreign bodies in the bladder, and of stagnation of urine.

*The medicinal treatment* is applicable to cases of persistent hyperlithuria, nephralgia, and very small uric acid concretions, but is of no avail as a solvent of medium sized or even of small calculi. It has long been supposed that alkalis taken by mouth and excreted by the kidneys act chemically upon uric acid stones, forming soluble salts, and so disintegrating these stones. Such, however, according to Denamiel, is not the case. He believes that much good is accomplished by the use

of alkalis, that they act little, if at all, directly upon the saline constituents of stones, but rather upon their mucous cement, thus disgregating without disintegrating the calculous particles and rendering the stones inordinately friable. In persistent hyperlithuria, continuance of the medicinal part of the preventive treatment, and the use of solutions of salts of potash, soda, and lithia—natural preferable to artificial solutions—in moderate doses for two or three weeks ordinarily fulfil the indication of dissolving uric acid sand and of preventing the formation of stone, besides relieving the irritation caused by the sharp-pointed crystals. Soap pills, and potash and soda solutions, long continued, greatly disturb digestion and even tend to increase uric acid formation.

*The palliative treatment* is indicated in patients who are enfeebled by intercurrent disease or by grave lesions of the urinary organs caused by the presence of a stone which cannot be safely removed, and comprises medicinal and mechanical means designed to mitigate pain and prolong life. In such a case the failing strength of the patient is supported by suitable food and mild stimulants. The teasing spasms of the bladder are relieved by the judicious use of belladonna, and the pain assuaged by opium. Much comfort can be obtained from cleansing the bladder with acidulated warm water, which tends to counteract the bad effects of ammoniacal urine; from occasional vesical injections of mucilaginous decoctions; and, in the case of phosphatic calculus, from irrigations with acetate of lead solution, which may cause such a decrease in the volume of the stone as materially to mitigate the suffering. Hot fomentations to the hypogastrium, hot hip baths, posture, etc., and all useful adjuvants.

*The mechanical treatment* consists in the application of means adapted to the removal of calculous concretions by the natural route to the bladder or by an accidental or an artificial route to the urethra, bladder, ureter or kidney, according to the particular exigency.

Preparatory treatment is needed in the great majority of cases. The required instruments are rendered aseptic, and all operations are performed with antiseptic precautions, even simple catheterism.

For the purposes of surgeons the mechanical treatment of urinary concretions is arranged into lithecboly, lithexaeresy, litholysy, lithotomy and lithotripsy.

**Lithecboly**—the casting out of stone, stone expulsion—occurs spontaneously, but is often brought about by artificial means, medicinal or mechanical, generally by both combined. During spontaneous lithecboly the stone has been known to perforate the renal pelvis or the ureter and finally make its exit through the lumbar region, or enter the peritoneal cavity and cause fatal peritonitis. It has made its way from the bladder to the rectum, from the urethra to the perineal or the scrotal connective tissue, sometimes giving rise to the fatal infiltration of urine. Therefore when spontaneous lithecboly has begun it should be aided by judicious artificial means.

**Lithexaeresy**—the extraction of calculi—is resorted to when the bladder contains small calculi or fragments that can be removed by means of specially constructed forceps, by the spoon lithotrite, and also by hydro-pneumatic aspiration, or, when such calculi lodge in the urethra, by means of forceps adapted to the urethra.

**Litholysy**—the dissolution, or more properly the decomposition of stones in the bladder—is applicable only to phosphatic stones; the agents proposed for the dissolution of other stones being of such a nature as to destroy the bladder before acting upon the stone. They are therefore rejected. One of the most efficient methods of litholysy applied to phosphatic stones is that suggested by Dr. Hoskins, of Guernsey. It consists of vesical irrigation with an aqueous solution of acetate of lead rendered clear by the addition of a trace of acetic acid. By this method there is no dissolution, but a double decomposition, resulting in the formation of an insoluble phosphate of lead in an impalpable powder, and a soluble acetate of the bases. Another method that often renders much service in the case of phosphatic gravel, or stone, is the daily irrigation of the bladder with warm water, to which may be added one minim, and sometimes two minims of hydrochloric acid to the ounce.

**Lithotomy**, in the sense of cutting for stone, embraces nephro-, uretero-, cysto-, and urethrolithotomy.

**Nephro-lithotomy** means to cut open the kidney for the extraction of a stone or several stones lodged in a calyx, in its pelvis, or in its substance, whether the calculus or calculi fill the pelvis or have partly obstructed the ureteric orifice and caused pyonephrosis. The operation is generally performed through the loin, and is indicated when, medicinal treatment having failed, the distress caused by the stone is unabated, the urine continues to be purulent with occasional copious admixture of blood and small calculi or particles of the main calculus. When it has not been too

long delayed, nephro-lithotomy has given good results, and a very small mortality. The exploratory operations have not been mischievous though many have been performed and no stone found.

In the lumbar operation the renal pelvis is sometimes directly opened without interference with the substance of the kidney. In this case the operation is strictly a pyelo-lithotomy, rather than a nephro-lithotomy.

**Uretero-lithotomy** may be performed in two situations; first, by a preliminary trachoeleocystotomy, when the calculus is lodged at or near the lower extremity of the ureter; second, in the lumbar region, but in this region the diagnosis of impacted calculus is attended with many difficulties. If, however it be made, it is possible to incise the ureter longitudinally upon the stone, after whose extraction the ureteric wound can be stitched with very fine silk properly sterilized. The objects being to prevent a lumbar urinary fistula, and to avoid nephrectomy. It is also possible to perform uretero-lithotomy near the sacro-iliac synchondrosis through an incision such as is made for ligature of the primitive iliac artery.

**Cysto-lithotomy** has been performed in modern times with much greater frequency than lithotripsy, partly because the indications and contraindications of these two operations have not been as generally studied as they merit. There are too many surgeons who perform exclusively cysto-lithotomy or lithotripsy, instead of striving to adapt to individual cases the modes of treatment which are most likely to meet their requirements. This is probably owing to the fact that there are good lithotomists who have never been able to perform lithotripsy with success, and skilled lithotritists who have not taken the pains to acquire a practical knowledge of lithotomy. Both operations are indeed very difficult and demand patient study, as well as carefully conducted experiments on the cadaver, before they can be intelligently practiced upon the living. In lithotomy, success is not attainable without this preliminary training. In lithotripsy, failure to acquire the necessary manual dexterity and delicacy of touch after repeated trials on the dead clearly shows that upon the living this operation can be safely undertaken only by those who have attained the requisite skill.

The desirable and objectionable features of the different cutting operations for ridding the bladder of a stone or of several stones are so closely balanced that it is difficult to state with precision in what may consist the superiority of one method over another.

When it is decided that cysto-lithotomy shall be performed, the question naturally arises, what special method seems best suited to the case? A cursory review of the origin, features and results

of each method may aid in the settlement of this question.

The operations of cysto-lithotomy are arranged into the infra-pubic and supra-pubic.

The infra-pubic operations comprise the perineal and the recto-vesical.

The perineal operations are : the lateral, the medio-lateral, the bilateral, the prerectal, the medio-bilateral, the median (Berlinghierian), the median (Allartonian), lithoclastic trachoeo-cystectomy (Dolbeauian), and modifications of most of these methods.

The recto-vesical operations are : the external urethro-recto-vesical (Sansonian), the external recto-vesical (Sansonian), the internal recto-vesical (Sleighian), and their modifications.

The supra-pubic operations comprise many modifications of the original Franconian method to the present time.

Lateral perineal cysto-lithotomy is indicated : in young children, to whom, however, all the methods of perineal lithotomy may be applied with greater success than to adults ; in adolescents whose bladders are unduly irritable ; and in the case of those adults who are suffering so much from cystitis that complete drainage of the bladder is of as much consequence as extraction of the stone.

This operation is contraindicated in patients suffering from calculi of small size that can be destroyed at one or two lithotriptic sittings, or in cases of friable calculi of one inch or even one inch and a half in mean diameter where the bladder may tolerate a prolonged sitting with extraction of the fragments. It is also contraindicated in cases of elderly men suffering from urethro-vesical prostatic obstruction. In such cases trachoeo-cystectomy with median incision or excision of the "bar," or tumor, as the case may be, is likely to fulfil the two indications of relieving the obstruction to urination and of permitting the extraction of the stone.

The desirable features of the lateral method are : it affords an ample outlet for stones of medium size ; it effects complete drainage of the bladder ; and it is particularly suitable in young children and also in adults when the bladder needs rest and efficient drainage.

The principal accidents of this method are : failure to reach the groove of the staff and consequent injury of the adjacent parts ; wound of the rectum ; wound of the interior of the bladder ; excessive hæmorrhage ; urinary fever ; infiltration of urine ; laceration of the vesical neck in forcible extraction of a large stone ; general cystitis ; peritonitis ; and pyosapremia. Most of these accidents are common to the other methods of perineal lithotomy.

In the lateral and in most of the other methods of perineal lithotomy, injury is very rarely done to the seminal ducts with the knife. These ducts

are, however, very liable to be destroyed by the general laceration incident to forcible extraction of large calculi, the result to the patient being impotency. On this account all stones exceeding one inch in diameter should be broken before extraction.

The mortality from the lateral method is computed at 12 per cent. The great majority of deaths after lithotomy are, however, attributable to long-existing disease of the urinary tract, rather than to the operation itself. Probably the best results ever obtained by any individual surgeon were those of Dr. Dudley, of Kentucky, who operated by the lateral method upon 225 patients, only seven of whom died. Dr. Valentine Mott had performed lithotomy fifty times and lost only one patient, afterwards he had more fatal cases.

The medio-lateral operation, performed upon a rectangular staff by Sir James Earle, Dr. Nathan R. Smith, and Dr. Mercier, was, in 1846, adopted by Dr. Buchanan, of Glasgow, who asserts that it is of easier and more rapid execution than the lateral method ; that it is less formidable owing to a more limited division of the parts ; and that the risks of hæmorrhage, injury to the rectum, and infiltration of urine, are less than in the lateral method. The operation has many times been performed by Dr. Buchanan, Dr. Lawrie, Dr. Alan P. Smith, Mr. Henry Lee, and others. The mortality is about 10 per cent.

The bilateral operation has for its main feature the double incision, which permits the extraction of a larger stone than can be safely removed through the tract of the unilateral incision. The mortality from the bilateral method in the time of Dupuytren was over 20 per cent. It has since been reduced to about 11 per cent. in the practice of the late Dr. Paul F. Eve, whose records show eight deaths in ninety cases, in the last forty-five of which, however, only two deaths occurred.

The prerectal operation, according to Nélaton, has for its main feature the avoidance of the urethral bulb. The bugbear of excessive hæmorrhage from division of the bulb has led to many unnecessary and sometimes hurtful devices for avoiding this bulb, which, in point of fact, is almost always cut, in perineal lithotomy, and seldom bleeds excessively when it is freely divided ; a slight wound being more likely to bleed profusely. To Mr. Skey lithotomists are indebted for exposing this fallacy. The results of the prerectal are about the same as those of the bilateral method, of which it is but a slight modification.

The medio-bilateral operation, proposed and performed in 1829 by Civiale as an improvement on the bilateral method, consists in making a median external incision including the urethra, and in using, for the deep incision, a straight-bladed instead of the flatwise-curved-bladed double lithotome. Civiale's advocacy of this valuable

method is owing, as he says, to its easier execution than the operation of Dupuytren, and to its occasioning less hæmorrhage. This operation has been performed with great success by Dr. W. T. Briggs and others. Dr. Briggs and the late Dr. J. C. Hutchinson have employed a double lithotome similar to Amussat's. Others have cut with a single-bladed lithotome, thus making a veritable medio-lateral operation. Dr. Briggs has performed the medio-bilateral operation upon 136 patients with only three deaths.

The median (Berlinghierian) operation, suggested by the Marianian, consists in making a median perineal incision, in opening the urethra at its bulbo-membranous junction, and in incising the prostate and vesical neck in the median line. Vacca Berlinghieri proposed it as a substitute for the external urethro-recto-vesical operation of Sanson. The liability of wounding with the knife, or of lacerating during extraction, the rectum or ejaculatory ducts, renders this operation very objectionable. It is, however, the only method to which strictly the name of median lithotomy can be applied.

The median (Allartonian) operation opens a route to the bladder permitting the safe extraction of only small and medium-sized stones. Large stones, of 2 or more than 2 inches in diameter, have been easily extracted, during this operation, from adults, and proportionately large calculous masses from adolescents and children, but only in cases of very soft and extraordinarily extensible prostates. Under ordinary circumstances forcible extraction is as hurtful in the median as in other perineal operations. On this account Mr. Allarton advises that the larger stones be broken up and their fragments extracted.

This method of lithotomy is indicated in children, in adolescents, and in adults whose bladders do not require drainage. It is indicated also in elderly men suffering from prostatic obstruction due to urethro-vesical "bars" which need incision or excision, and when the combined operations of lithotomy and prostatotomy or prostatectomy may be advantageously performed.

The median operation is contraindicated when the bladder requires drainage, and of course when the indications for lithotripsy are plain.

The desirable features of the Allartonian method are: the median incision, by which excessive hæmorrhage is avoided; dilatation instead of incision of the prostate and vesical neck; and little if any liability to infiltration of urine. As ordinarily performed it is not so difficult as the other methods, except in cases of very hard prostates, and in very young children whose urethræ have been torn across and even severed from the prostate in the attempt to dilate the prostatic region with the finger. It is therefore wise to substitute for the finger a metallic dilator such as that devised by Dolbeau. The mortality from the Allartonian operation is about 10 per cent.

Lithoclastic trachæo-cystectomy, otherwise known as perineal lithotomy, when stripped of the details prescribed by Dolbeau for its performance, bears much resemblance to Allarton's method except in the accomplishment of the dilatation—to the extent of  $\frac{1}{8}$  of an inch—which is made with a specially constructed instrument much safer in its application than the antero-posterior digital dilatation of Allarton. Another difference between Allarton's and Dolbeau's methods is that, in the first, medium-sized stones are removed entire and larger stones are fractured before extraction, while in the second case the operation is intended only for large stones which are to be fractured before extraction. Like Allarton's method, this operation is not applicable when the bladder requires drainage.

The mortality from lithoclastic trachæo-cystectomy in Dolbeau's hands was at the rate of about 16 per cent. In view of the fact that Dolbeau's cases were of large stones, this death-rate may be regarded as small, since the mortality from other methods of perineal lithotomy without lithoclasty, for large stones, was formerly 30 per cent.

The external urethro-recto-vesical and the external recto-vesical operations of Sanson have long ago been abandoned. The external wound, continuous with the urethra, prostate and rectum, in one case, and the great liability to urinary fistula in both cases, render them very undesirable.

The internal recto-vesical method of Sleigh has been advocated partly because no other than the recto-vesical wound is inflicted. But even in this case urinary fistula has ensued. Its alleged advantages are: the absence of inordinate hæmorrhage, and the facility with which a large stone is extracted. In later years the wound has been successfully closed with silver sutures, and in one instance with the aid of Bozeman's button suture.

The accidents of recto-vesical lithotomy are, infiltration of urine, wound of the ejaculatory ducts, and wound of the peritoneum. The mortality is computed at about 19 per cent.

Supra-pubic cysto-lithotomy, condemned by Franco, its inventor, and urged by Rousset, who never performed it, lingered for a century and a half, when it was suggested by James and put into practice by John Douglas; performed for a time by Cheselden and modified by Frère Côme and others, again abandoned, then revived by the Souberbielles and by Amussat, was finally, on account of the mortality it occasioned, very exceptionally performed until these late years, when it was reinstated with improvements that now render it comparatively safe.

The operation is indicated in cases of large compact stones too hard to be broken in perineal cystotomy or cystectomy, in cases of such stones complicated with prostatic "bars," or tumors requiring incision or excision, in cases of stone with tumors of the bladder, and in cases of foreign

bodies in the bladders of patients suffering from prostatic obstruction, when these foreign bodies cannot be extracted by the natural route. In such cases the bladder must be ample, although the supra-pubic operation has been successfully performed when the capacity of the bladder has been markedly diminished.

For supra-pubic intra-vesical prostatectomy, a rectangular instrument, constructed on the principle of Skene's hawk-bill scissors, such as this now exhibited, may be employed with advantage. This intravesical prostatectome, made by Tiemann & Co., answers well the purpose of excising a V-shaped portion of the enlarged prostate. Mr. Stohlmann has promised to make an instrument of the same sort, capable of cutting a U-shaped segment. Pedunculated tumors of the prostate may be excised with rectangular short-bladed scissors adapted to the supra-pubic operation. The intravesical operations upon the prostate will be facilitated by electric illumination of the cavity of the bladder.

Urethro-lithotomy is described by Celsus as performed in the phallic region. This method of removing urethral calculi continued to be employed until the invention of lithotripsy, since which time the cutting operation has been abandoned, except in cases of very large stones. Urethro-lithotomy is now generally performed in the scrotal, perineal, membranous and prostatic regions. It is indicated in cases of urethral calculi complicated with narrow undilatable strictures, and in cases of large stones lodged in these several regions of the urethra when urethro-lithotripsy is not practicable.

Lithotripsy, the reduction of stone to small fragments, to a granular state, or to a powder, suggested probably by the observation of spontaneous fracture of stones in the bladder, by the lithotomy of Ammonius, by the lithoclasty of Franco and the Colots, and developed from the primitive contrivances of Paré, of Sanctorius, of Fabricius Hildanus and of Gruithuisen, satisfactorily demonstrated, in male patients, only in the first quarter of this century, could not at first be rightly valued, as too much was promised for, and expected of, the new operation with its complicated appliances. It over-zealous advocates endeavored to grade it above all other modes of treatment, and particularly to establish it in place of cutting operations, but at length acknowledged that it failed to supersede lithotomy and must be regarded solely as an additional resource of surgery, to be applied with proper discrimination in a particular class of cases. Nearly half a century of experience was needed to give lithotriptic instruments their present degree of simplicity and to enable Civiale and others to formulate proper rules for the guidance of those who undertake the operation.

The operations of lithotripsy comprise cysto- and urethro-lithotripsy.

Cysto-lithotripsy includes: lithotripsy by the natural route to the bladder; by an accidental route, *i. e.*, through a perineal fistula; and by an artificial route, *i. e.*, through a perineal incision.

Cysto-lithotripsy consists of: lithotripsy in multiple short sittings; in one or two long sittings, with extraction of the detritus by means of the spoon lithotrite; and in a single prolonged sitting, with aspiration of the detritus.

Urethro-lithotripsy includes: urethro-lithotripsy by the natural route; by an accidental route, *i. e.*, through a urethral fistula; and by an artificial route, *i. e.*, through a urethral incision.

Cysto-lithotripsy is indicated in cases where the stone is free, friable and of small or medium size. Under favorable circumstances stones of larger size may be crushed, and within certain limitations, plurality of stones is not a contraindication. The further requirements are, that the patient shall be in an otherwise good physical state, that his urethra shall be ample or susceptible of being safely rendered so, and that his bladder shall tolerate the necessary instruments.

The existence of stricture is not a contraindication of cysto-lithotripsy provided the urethra can be freely dilated or even enlarged by internal incision, but a narrow stricture in the perineal region, especially if it be of traumatic origin, contraindicates lithotripsy by the natural route and generally demands a cutting operation.

Urethro-vesical obstruction, unless very extensive, does not contraindicate lithotripsy. Contracture of the vesical neck often subsides soon after removal of the detritus. But in cases of thick "bars" at the neck of the bladder and tumors of the prostate, lithotripsy is not always practicable and cutting operations are sometimes required.

When the bladder walls are much thickened, when this viscus is permanently contracted, when its capacity is markedly diminished, or when it is inordinately irritable, provided the kidneys be not diseased, perineal cystotomy is indicated and lithotripsy contraindicated.

Advanced disease of the bladder, ureters and kidneys contraindicates both lithotomy and lithotripsy.

The worst results of lithotripsy, outside of France, until about twenty years ago, gave a mortality of 20 per cent., and the best results 9 per cent., the average being about 10 per cent., in a total of 992 operations.

Up to the year 1884, Sir Henry Thompson's own record shows a mortality from lithotripsy, in a total of 672 cases, of "forty-three, one death in fifteen cases, or under 6.5 per cent.;" while the deaths from lithotomy, also in his practice, were "thirty-nine in 110 operations, or 35 per cent."

To choose properly between cysto-lithotripsy in multiple short sittings, in one or two long sittings with extraction of the detritus by means of the spoon lithotrite, and in a prolonged sitting with

aspiration of the detritus, requires sound judgment based not only upon experience but upon careful consideration of the peculiar circumstances of each case. Therefore only general rules for guidance can be formulated, and these rules are varied to suit particular cases.

As a general rule multiple short sittings, of from one to three minutes, are applicable to patients whose bladders are only moderately tolerant and do not fully respond to ordinary preparatory treatment. Three or four such sittings, each with a single introduction of the lithotrite, four or five days apart, being ordinarily sufficient to cause the spontaneous expulsion of all the detritus of a friable and granular stone 1 inch in mean diameter.

One or two long sittings, say ten or fifteen minutes each, with five or six introductions of the spoon lithotrite, as recommended by Heurteloup under the name of lithocentesis, sometimes suffice to remove, from a tolerant bladder, the major part of a friable stone 1 inch or  $1\frac{1}{4}$  inch in diameter; the remainder of the detritus being spontaneously expelled.

Cysto-lithotripsy at one sitting with aspiration of the detritus is said to be indicated when the stone is large and when there exists urethro-vesical obstruction; but it is often performed in violation of both of these indications. Note the many reported operations of "litholapaxy" for stones capable of being destroyed at a single two minute sitting. Another notable fact is that some of these reported cases were not cured at one sitting, but required two, three, and even four sittings, each followed by aspiration. The operation is named rapid lithotripsy as well as "litholapaxy," although it lasts from fifteen minutes to two hours. The sittings of ordinary cysto-lithotripsy average two minutes. If there be four sittings, only eight minutes are consumed in all for the safe trituration of the stone. This is indeed a rapid process, but prudence demands that there be intervals averaging four days between the sittings, or twelve days in all to effect a cure. Many cases of stones of  $\frac{6}{8}$  of an inch diameter are, however, cured at a single sitting of three minutes without the aid of anaesthesia or aspiration, and with scarcely any pain.

Much may be said against the single sitting with aspiration of the detritus, when this sitting is prolonged one or two hours, as suggested by Dr. Bigelow. The urethral and vesical irritation caused by the repeated passage of the lithotrite and of the tubes for aspiration, the violence done to the bladder by the beak of the lithotrite in the many seizures of calculous fragments, the friction and perhaps the erosion of the mucous membrane by angular fragments during search for these fragments, and the several aspirations with sudden and frequent distension of the bladder are, to say the least, serious objections to the one pro-

longed sitting. The process of aspiration is itself so much more painful than the crushing of the stone and fragments (acting much of the time, in the hands of the inexperienced, like a cupping glass upon the vesical mucous membrane and contusing it in many places), that anaesthesia is rendered necessary, and this also is a grave objection, considering the fact that anaesthesia is to be prolonged one or two hours, particularly with the aid of sulphuric ether, whose ill effects upon the kidneys are now so well known. Is it not safer, in cases of large stones, to replace prolonged "litholapaxy" by suprapubic lithotomy or by lithoclastic cystotomy or cystectomy, and thus avoid exposing patients to the risks of general cystitis and pyelo nephritis, or to acute parenchymatous nephritis from the elimination of a large quantity of ether?

Aspirations of calculous detritus are often advantageous, particularly in cases of urethro-vesical obstruction, but need scarcely last longer than two minutes. Such aspirations, practiced with the utmost gentleness, can safely be made with Dr. Bigelow's excellent and most ingenious instrument, immediately after each three minute sitting at lithotripsy, though the case require three or four sittings in the course of two weeks.

Lithotripsy at one prolonged sitting cannot with prudence be generalized. The majority of cases of stone can be treated with greater safety to patients by other methods which leave behind no untoward vesical trouble. The early writers on "litholapaxy," allured by some brilliant results, hastily recommended it, and had many followers who, however, were soon disappointed by discovering that the new method is more difficult and more dangerous than the old, and that it requires no less discrimination. There are surgeons who still perform the operation at one prolonged sitting, notwithstanding that the effects of one or two hours' trituration of a stone and aspiration of its fragments are known to be so injurious and to be so much more grave than the irritation caused by fragments made in ordinary lithotripsy, which has for one of its objects the granulation and partly the pulverization of the stone.

"Litholapaxy" is no longer a novelty; it has been performed several hundred times since the year 1878, and may now be estimated at its right value. The great expectations of its advocates are not realized, for they have discovered that the operation cannot always be terminated at one sitting, that it is not suitable in a number of cases of large stones, that it is not applicable in many cases of stone complicated with prostatic obstruction, that it has been too often misapplied, by the over-zealous, in cases of medium-sized and even small stones amenable to ordinary lithotripsy in one or two short sittings, that in too many cases the injury inflicted upon the bladder has led to chronic cystitis and to the formation of phosphatic stones,

and that the necessarily prolonged anæsthesia is too dangerous to be generally employed.

"Litholapaxy," applied to a very limited class of cases, is a very good operation, in the hands of skilled and experienced lithotritists, but too much of an undertaking for beginners or for those who are not constantly occupied with surgery.

Respecting lithotripsy in children, only a few words will be said.

Lithotripsy was successfully applied in 1827 by Civiale to an ill-developed child 7 years of age suffering from a large vesical stone. In 1834 Ségalas reported a case of stone treated by lithotripsy in six sittings in a child aged 33 months, the stone measuring "11 lines." He subsequently recorded four additional cases in children aged respectively: 40 months, stone 10 lines, four sittings; 45 months, stone 13 lines, ten sittings; 4½ years, stone 1 inch, six sittings; 5 years, stone 15 lines, twelve sittings in two months; and no deaths. In 1838, Nathan R. Smith performed lithotripsy successfully upon four boys, of whom one was under 2 years of age, another 3 years, and the other two 7 years. In 1839 John Randolph performed this same operation upon two boys, one aged 4 years and the other 11 years, both cases being successful. In 1836, Leroy also wrote of lithotripsy in young children, and Guersant, who operated upon twenty-one children, lost six. Mercier (1862), Beyran (1863) Fournier (1874), Gonzalez (1883), and others, all spoke their word concerning lithotripsy in children, and the final conclusion of those whose testimony carries the most weight was that it should be reserved for cases of small stones requiring only one short sitting. Sir Henry Thompson, whose number of lithotriptic operations exceeds that of any other living surgeon, records, up to the year 1884, only three lithotrities upon children.

Dr. Keegan's success with lithotripsy and "litholapaxy" in children is likely to lead many young surgeons to the wrong use of these operations, and many will be the ill consequences of such a violent procedure as "litholapaxy." In some of the children subjected to "litholapaxy" by Dr. Keegan the detritus weighed only a few grains and could have been easily expelled spontaneously after simple lithotripsy, and he counts these cases among the triumphs of "litholapaxy;" and in other cases the stones exceeded 200 grs. in weight. In the first instance, simple lithotripsy was clearly indicated, while in the second, both lithotripsy and "litholapaxy" were clearly contraindicated. Of Dr. Keegan's first seventeen cases of "litholapaxy," in children aged from 20 months to 12 years, only one patient died. This speaks well for the tolerance of the patients' bladders and for the skill of the operator, but even if the percentage of mortality should, in future, be no greater in other cases of children between the ages of 20 months and 12 years, it would not render the op-

eration justifiable in children of 5 or under 5 years of age.

Lithotripsy would long ago have been largely performed in such children if it had been found generally safe. In cases where the stone is friable, small, weighing a few grains, lithotripsy is not only justifiable, but the proper operation, provided the urethra easily admit a suitable lithotrite; but to combine aspiration with such an operation is, to say the least, unnecessary.

Lithotomy is assuredly the safer operation in such children when the stone exceeds ½ inch in diameter, but when it is too large to be extracted, lithoclastic cystotomy is essential to success in the majority of cases.

Sir Henry Thompson gives a table in which it appears that of 473 lithotomies performed upon children of from 1 to 5 years of age, thirty-three died, or one in fourteen and one-third cases; and of 377 operations upon children of from 6 to 11 years of age, sixteen died, or one in twenty-three and one-half cases. Lithotripsy in children has not yet given such results on the same scale.

The general conclusion drawn from this study is that a proper choice of treatment of urinary concretions can only be made after careful consideration of each method and each case, there being no generalizable method.

## YELLOW FEVER.

*Read before the State Medical Society of Arkansas, Pine Bluff, Meeting May 28, 1889.*

BY WOLFRED NELSON, C.M., M.D.,

MEMBER OF THE COLLEGE OF PHYSICIANS AND SURGEONS, PROVINCE OF QUEBEC, CANADA; LATE STATE BOARD OF HEALTH, PANAMA, SOUTH AMERICA, ETC.

With your kind permission I shall read a brief paper on yellow fever, a theme at once interesting to all students of medicine, and presumably of marked interest to my *confidères* in the "Sunny South."

In what follows I shall refer to my own experience of this dread disease at Panama on the Pacific, Colon on the Atlantic, both ports of the Isthmus of Panama. My studies and observations on the west coast of Mexico, where in 1885 I traced its epidemics of 1883 and 1884. My experience in the hospitals of Cuba, and finally my visit to Florida, in the fall of 1887, when I deliberately forecast the epidemic that swept Jacksonville in 1888. My letter of warning to the people of Florida was published in the *Times-Union*, of Jacksonville, November 30, 1887, and was recalled *when the disease was upon them*.

Now, to return to the Isthmus of Panama, where I lived and practiced from 1880 to 1885. I was back there twice in 1886 and twice in 1888, thus, to use an expressive phrase, bringing my knowledge down to date.

The yellow fever of the Isthmus of Panama I

describe thus: It is an acute infectious disease, a specific fever, ordinarily not contagious, but under certain atmospheric conditions, not yet fully explained, the disease undoubtedly develops contagious properties and epidemics result.

Yellow fever is ushered in in a variety of ways. It may be preceded by languor or malaise. The invasion may be abrupt. Generally characterized by a chill, often very severe, lasting one, two or three hours; the duration of the chill having a marked significance, severe chills marking nearly all fatal cases. Again, the disease may be ushered in by sudden nausea and faintness, without any warning, as in my own case during the Isthmian epidemic of 1880. Headache is always met with. I know of no exception to this statement. Frontal headache, a flushed face and gastric irritability in newcomers within the yellow fever zone is always very suspicious, a fact specially referred to in Dr. Belot's admirable book, *La Fièvre Jaune à la Havane*. Generally the headache is frontal; it may be bi-parietal and occasionally occipito frontal, but, to repeat, marked headache always. In dealing with specific yellow fever of the Isthmus of Panama—of which, if respectability depends on its antiquity, is the oldest, most respectable and fatal variety known—a history of constipation obtains in nearly all cases. I can recall but a single case in my practice where the disease had been preceded by malarial diarrhoea. No condition of health gives immunity. It aims at all, be they healthy or unhealthy. It has a specific rôle. From early youth to advanced age it pursues its death-dealing mission. It is true that the mortality among children is less than at puberty and beyond. Pains in the legs and sacral region, the latter often intense and agonizing. I shall never forget my own experience. It seemed as if a legion of fiends were trying to dig out—if I may use the expression—my sacrum with red-hot pincers. The pain is excruciating and indescribable. In the majority of patients, the face was red, just like the face in scarlet fever—the boiled lobster color. The eyes at first were clear, providing there had been no antecedent hepatic disease; later they became suffused, injected. The skin was hot and dry. In many cases a peculiar biting heat was felt (like the *calor mordax* of pneumonia). It produced a strange sensation, resembling a current of electricity playing over the extended palm. Pulse hard and slow, varying from 65 to 80. Temperature, first stage 100° to 103°, where the cases proved fatal in the first stage, rising to 104°, 106° and 107°, the latter being the highest temperature noted by me in my practice. To fall slightly just before death. In the second stage or "period of calm," as it is termed, it fell, a remission only. At the beginning of the third stage or the stage of "secondary fever" it rises again. Respiration, as one would expect during the "hot stages," is hurried. At times a pecu-

liar moaning respiration of indescribable sadness. It fills the room and the vicinity. The respirations varied from 30 to 40 per minute, and at the close of the third stage 50 to 60, becoming less with the fall of the temperature just before death. Great thirst, nothing appeases it. Restlessness, no position giving any ease. Urine, at invasion, normal but high-colored. In the majority of cases on the Isthmus of Panama they died during the first stage. Such was the blood-destroying intensity of the disease, when all, or nearly all of the symptoms detailed and to be detailed, appeared. They do not appear in any stated order.

Within twenty-four hours of invasion, all the symptoms are intensified. Sacral pain and headache increasing. Gastric disturbances and epigastric tenderness developing early in many cases, the slightest pressure over the stomach causing intense pain and eliciting sharp cries. In cases where the brain symptoms were very marked, in some where patients were unconscious, the slightest pressure produced a contortion of the face and body. If deep-seated pressure was made they writhed upon their beds, but the instant that it was removed they became quiet again. Next, nausea and vomiting, at first a clear fluid, well named "white vomit" by Surgeon-General Blair, of British Guinea, South America. Tongue at first slightly coated. I am dealing with complicated cases. In patients who had suffered from intermittents, or bilious remittents, what is termed the characteristic tongue of yellow fever was not found. As stated, it was slightly furred. Later the fur increases from behind forwards, the tips and edges take on a deep red. Gums also become a fiery red, also the mucous membrane of the mouth and throat. The whole mucous tract suffers. Later, in the majority of cases, sore throat is complained of, due to stripping of the mucous membrane. Blood oozes from the denuded tongue and gums, giving an indescribable fetor to the breath; at times it collects on the teeth. In some cases a peculiar and characteristic odor is exhaled from the patient's body. Once recognized, it never will be forgotten. It somewhat resembles *l'odeur du cadavre*, of French authors. The late Dr. Stone, of Louisiana, was the first American writer, I believe, to recognize it. As he states, it is a very bad omen.

When patients die in the first stage, the urine always shows a large amount of albumen. The temperature remains high, 104° to 107°. Delirium, often quiet, marks the latter temperature. In some cases extending over more time—beyond the fourth or fifth day—the albumen does not appear until the close of the second or the beginning of the third stage. Albumen is a *sine qua non*. I know of no yellow fever without it, nor do any of my many friends practicing within the tropics. It never was absent in Isthmus cases. I never have seen or heard of a case of specific yellow

fever without it; never, either in the practice of Dr. L. Girerd, late Surgeon-in-Chief Panama Canal Company, in that of Dr. Didier, of the same service, or in the cases seen by my brother, the late Dr. George W. Nelson, at one time my partner, and later Resident Surgeon at the Canal Hospitals, Huerta Galla, Panama, giving a combined experience of hundreds and hundreds of cases. During an epidemic at Colon in the fall of 1883, it swept the shipping, over 150 cases, nearly all fatal. Again albumen in all cases. Suppression of urine is a late, and generally among the last symptoms. Where it is marked, they seldom recover. The bowels, if freely acted upon by the sulphate of soda, to be referred to, may not furnish any early information, diarrhoeal motions produced by the soda being followed by "black vomit motions" in many fatal cases. These motions may precede or follow black vomit. No rule is absolute, or such material, well named, may only be seen at the autopsy. Black vomit follows the constant retchings and the "white vomit" of Blair. Black vomit is happily named, and shows innumerable fine particles or flocculi named black vomit or "coffee ground vomit," or the *marc de café* of the French writers, whose books on yellow fever are among the latest and very best. Frequently patients, without the slightest warning, commence violent vomiting. It pours forth from mouth and nostrils, often threatening to choke them. I have seen a patient resting quietly on his back after the subsidence of the gnawing sacral pain, when a perfect flood of black vomit has spurted from his mouth and nostrils up into the air, over bedding, mosquito curtains and the nurse. An old and intelligent writer on yellow fever, Dr. Dowell, has been singularly happy in his remark, that it is *per saltum*. So it is.

Here, I must pause and divide my yellow fever cases into two classes, and shall state that such are met on the Isthmus of Panama. One class, I took the liberty of naming "uncomplicated," the other "complicated." By uncomplicated, I mean the disease occurring in new comers. In these, brain symptoms and delirium were common. Such, almost without the classic exception, died, I never knew one to recover. The possession of full health meant rich blood, and a better culture fluid for the germs, that destroy it; the absolute destruction of the blood being but a matter of three or four days. I can best illustrate this by a case in the practice of my valued friend, Dr. L. Girerd, to-day a retired practitioner living in Paris. In the case referred to, on the fourth day of the disease, he failed to get a single red corpuscle in the blood—not one. The heart was driving a fluid through the vessels—one incapable of nourishing the brain and tissues. A fluid wholly devoid of the life sustaining oxygen carriers, the red corpuscles. His crucial microscopic work revealed a fluid, and in it the débris of cor-

puscles; or, to use the old time word that I have applied to this condition in yellow fever, a necremia, or death of the blood. His patient, a titled foreigner, a magnificent specimen of manhood, who stood 6 feet 4 inches in his stockings, died a few hours later. The "complicated" occurred in those who had been on the Isthmus from six months to sixteen years, and of course were profoundly malarious. I say of course, as no man, woman or child there escapes intense paludal poisoning. Sixteen years had failed to give the so-called acclimation to an American, Captain Dean. Specific yellow fever cut him off. He was my patient. An elderly Italian, M. Georgetti, after thirty-seven years' residence at Panama, died of specific yellow fever. I personally know a French gentleman in Guaymas, Mexico, who has spent over forty years on both coasts of Mexico. He went through epidemic after epidemic unscathed, but in the thirty-sixth year of residence, after passing through the Guaymas epidemic of 1883, he came down with the disease in 1884, when a few cases appeared, as is usual following *all epidemics within the tropics*, and just escaped dying. He in person related his experience to me. Acclimation is only so-called; it is a myth, but quite in keeping with much of our gross ignorance regarding yellow fever. Nothing, absolutely nothing, protects against yellow fever—except having had the disease, a fact well known to all close students of the disease within the tropics.

With this digression as a preparatory statement, I shall next consider the second stage, or "period of calm," as it is termed. There is a marked fall of temperature, but merely a remission, and most deceptive and dangerous it is. I can best illustrate this by actual cases. In two cases, both mine, during the epidemic of 1880; new arrivals, just married; he a Frenchman and Consul for France; she a Portuguese, aged 17. They had passed the first stage. His temperature had run up to 106°, hers to 105°. Then came the deceptive "period of calm." They felt so well that, despite my emphatic orders, they got up and walked about. He was in one room and she in another. In the woman's case, the secondary fever came on that night, together with a copious "vaginal hæmorrhage," practically, the equivalent of black vomit. She died within twelve hours of her walking about her rooms. His temperature again ran up; he died the next day. She, poor girl, was laid out in her wedding finery. They occupy a single grave in the foreign cemetery at Panama. Such, gentlemen, is malignant yellow fever as I know it.

As I have stated, yellow fever may be a disease of a single "access" or paroxysm. When it is so, the patient dies or enters on convalescence—such being the milder cases at Panama. Thus, it resolves itself into a sharp, clearly defined fever of a single paroxysm, or "access," as the

French so expressively term it. As nearly all attacked died, the milder cases were the exceptions. In the great majority the "period of calm" was deceptive, the slightest imprudence on the part of the patient ending in death later. The remission—I have seen the temperature as low as 99°—lasting from twenty-four to thirty-six hours, in cases marked by long chills, but twenty-four hours, to merge into the third stage of the disease, or that of "secondary fever." I have faced three epidemics of small-pox, one at home in Montreal and two at Panama. The severe chills in that disease, initiating the severe and confluent cases, the high primary fever, the second stage, to merge into the high temperature of the secondary fever, consequent blood changes and death. These cases, so familiar to me, have caused much thinking in connection with my studies in yellow fever and its blood changes. In a fatal case of confluent small-pox, without the slightest warning, I have seen a fluid, that to the eyes was indetical with black vomit, spout from the mouth, high in air, over everything, staining the bedding just like black vomit; it was *per saltem*. To our life-currents we must look for information.

In the "third stage" the albumen appears, that is, if absent at close of "period of calm," it is invariably met here. Black vomit, and black vomit motions, suppression of urine, brain symptoms, etc., in cases ending fatally in this stage, all the symptoms crowd each other, and death closes the scene.

In "uncomplicated" cases, or where violent delirium may be met, many painful scenes result. A young Englishman, a picture of health, as attested by his magnificent physique and rosy cheeks, was stricken on landing. He was my patient. The case closed with furious delirium. Four men had to take turns in holding him, until death closed one of the saddest of sights.

A few words regarding the "fever of acclimation" of some writers. This, mark you, is generally preceded by a slight chill, a rapid pulse, a flushed face, suffused eyes, with a trace of albumen in the urine—in a word, it is a very, very mild form of yellow fever—the febrile movement lasting twenty-four to thirty-six hours, the mildest form of an "access." Failing a trace of albumen—it is not a fever of acclimation, that is to a tropical physician—and the other symptoms, no subsequent protection may be expected. In fact, some profound students of the disease within the tropics, consider it but a temporary protection, that in seasons of epidemic, while such are exposed in a lesser degree, still they are liable to contract the severe type.

Such, briefly told, is yellow fever on the Isthmus of Panama. I have seen and attended it in both cities, Colon and Panama. I wish to add, that it and other tropical diseases have caused, at a low estimate, fully 20,000 deaths on the line

of the Panama canal. The *New York World*, of May 18, 1889, credits the French Consul at Colon with saying that 15,000 Frenchmen have died. This probably is a mistake. I believe 20,000 all told, will be a generous estimate. The heaviest dying known to me was in November, 1884, during that epidemic at Colon, in the shipping and on the Isthmus. In an article in *Harper's Weekly* of July 4, 1885, I placed the death-rate for that month at 653 officers and men of the Canal Company. I obtained the figures from an inside source. The Canal Company's statements, as published in *Le Bulletin du Canal Interocéanique*, were as mendacious as they were misleading. DeLesseps' last ditch, that absurd creation of a man in his second childhood, has cost 20,000 lives, over \$200,000,000 in gold, has ruined hundreds of thousands of petty investors in France. Up to the hour of the crash, DeLesseps, in person, while knowing the whole truth, unblushingly told his fictions. Since 1884 he has known the whole truth. He is a wicked old man, who should be buried alive under his fictions.

Many of our confrères have fallen on the Isthmus. Some noble fellows are buried there—yellow fever, dysentery and pernicious fever. Yellow fever must be seen and studied in its own habitats. The Isthmus is one of the earliest.

My visit to Tampa, in November, 1887, impressed me in many ways, but what greatly interested me was to hear of cases of *non-albuminuric yellow fever*. These cases of so-called yellow fever, I believe, furnish that class of people who have had yellow fever two and three times. As may be inferred, I have no faith in any yellow fever without the invariable presence of albumen in the urine. I have yet to meet with or read of a well authenticated case of secondary yellow fever. Nor do I know of a single physician who has seen one.

Now I come to the subject of treatment; and here I most emphatically state that yellow fever has no treatment properly so-called. The host of so-called treatments justify my statements. How can a disease, according to the old view, characterized by the symptoms described by me, have one? Four centuries seem to have taught the profession nothing, or next to nothing. All that was known with absolute certainty was that people got yellow fever and died; the world heard of the dying, and that from Cuba it makes periodic invasions of the Sunny South. The treatment of yellow fever is purely symptomatic, my early treatment, up to 1884, was that of the "Old School." May God forgive it for its ignorance and charlatanism! Many authors have made a *rechauffé*, or re-hash, of the experience of others, they never having seen a case themselves. They are responsible for much ignorance, *if not worse*. Having tried all the so-called orthodox treatments, I, previous to the fall of 1884, settled on the following:

On being called to see a patient at the outset, I played a trump card and made quinine a diagnostic agent. We must bear in mind that a few hours in such cases may mean a life saved or lost. The following was the mixture :

R	
Quin. Sulph. . . . .	5j
Acid. Sulph., Dil. B. Phar. . . . .	5ij
Soda Sulph. . . . .	5ij
Tinct. Card Co. . . . .	5ij
Water, add. . . . .	3viij

℞ fiat mistura.

Sig.: Take a quarter at once and repeat in two hours.

This mixture, given French fashion, in *portions*, or portions, well diluted with water, made a perfect solution and was readily absorbed. It was my "multicharge gun." It gave me the best results. Hot baths. Pilocarpine in one case, aconite, etc., were in order, to produce free action of the skin. If the cases were purely malarial the quinine and sulphate of soda met all the indications. The sulphate of soda acts like a charm, free, bilious motions following. Every dose contained 15 grains of quinine and  $\frac{1}{2}$  ounce of sulphate of soda. If after two doses the temperature remained high, 100° and upwards, with the usual symptoms, yellow fever was the verdict. Valuable time had been saved, the bowels freely acted upon—a most important indication. Later, I added to this treatment the following: A phosphoric acid mixture every hour or two, largely diluted with water; gave it and it only, purposely to bring about an acid condition of the blood. In a few words, to make it wholly uninhabitable to the germs. I adopted this course, only after serious thought, and said to a medical friend, "My next patient with yellow fever gets well or dies on phosphoric acid." I explained it to two friends, Dr. L. Girerd and Dr. Arthur Gore, who saw my cases. Also, to Dr. Bransford, United States Navy, who crossed the Isthmus on his way to Nicaragua. Previous to my adopting this purely acid treatment, following the quinine and soda mixture, my patients kept on dying in a way that was simply appalling. Not that I lost more than my confrères. Our helplessness dazed me. As stated, after mature deliberation, I settled on phosphoric acid, well diluted, for life or death. Three cases so treated, all in succession, got well, an absolutely unheard of thing there. I had friends see them—knowing as I do, what unbelief and professional jealousy will do. My reasoning was sound. The acid did not destroy the oxygen-bearing function of the red corpuscles, while the germs of yellow fever did, and so killed my patients. By rendering the blood acid these germs could not live and reproduce. They were destroyed *in situ*, and the blood ceased to be a culture fluid. Any student of medicine familiar with bacilli and their cultures knows full well, that even faintly acid solutions are fatal to the propagation of bacilli. Such was my reasoning

as far back as 1884. I have the notes on those cases. I took full notes on all my cases, as I had been taught to do, while a student at the Montreal General Hospital, 1868-72.

The blood is the habitat of the germ of yellow fever. When my first case in the series of three demanded my attention, alas, I could not procure a reliable phosphoric acid, when I had to fall back on a formula published on page 93 United States Dispensatory, being that proposed by Mr. James T. Shinn, *American Journal of Pharmacy*, October, 1880, thus: "*Liquor Acidi Phosphorici*. A similar preparation under the name of Horsford's Acid Phosphate has a large use in this country. The formula is as follows: *Liquor acidi phosphorici* (without iron): Calcii phosphat., 384 grains; magnesii phosphat., 256 grains; potassii phosphat., 192 grains; *acidi phosphorici* (60 per cent.), 640 minims; aq., q. s. to make a pint." As stated, not being able to secure a reliable phosphoric acid, I was forced to use Horsford's Acid Phosphate. It, as I knew, was a standard preparation of uniform strength and excellence. I strongly object to employing a patent preparation, so to speak. Its contents or make up was known and it was "Hobson's choice." The preparation did all that I anticipated, and I give its formula as found in the United States Dispensatory. I know what I used. It is essentially a strong acid mixture.

To repeat, having given my quinine and sulphate of soda mixture, thus securing free motions from the bowels. The malarial element being eliminated by the non-effect of the quinine, I then treated for yellow fever, thus: To bring about free action of the hot and burning skin was absolutely necessary. As stated at first, I tried hot baths, aconite, etc., and abandoned them, using a simpler and more effective means, in a vapor bath, named in Peru "Dr. Wilson's treatment," being that of an English physician, who used it with great success during an epidemic there in 1854 and later. The patient was placed on a chair—one with a wooden seat—all clothing being removed; he was covered with blankets tucked in closely under the chin. A spirit lamp was lit and placed under the chair, thus giving heat and vapor. To Dr. Wilson's vapor bath, I added a foot bath, all under the blankets, the water as hot as the patient could bear it. Finally I grafted on some Jamaican treatment, giving a pint of hot lemonade or orange-leaf tea. Under this triad a profuse perspiration followed, usually within ten minutes, it fairly ran off them. As soon as it was freely established they felt better. The scarlet line of the face faded. The hard pulse became softer. If the bath caused any tendency to faintness, that was guarded against by a shorter exposure. With this I had no unpleasant symptoms, but with nitrate of pilocarpine profound pallor and faintness in a well nour-

ished man caused me alarm. I tried it in but a single case, and that was previous to my knowing of Wilson's vapor bath. The necessary exposure being made, ten to fifteen or twenty minutes, the patient stood up, the chair was slipped from below the blankets and he was lifted into bed *en masse* to prevent any escape of heat or moisture. More blankets were put over him. In some cases the perspiring lasted one or two hours, to the marked relief of the patient and the lessening of all the symptoms. After a variable time the skin again became hot and dry, when the same procedure was repeated as often as necessary. Thus two highly-important indications were met at the very outset. First, under the quinine and soda, free motions from the bowels were secured. Remember the marked constipation in these cases, often extending over three or four days, while the man had been eating as usual. Secondly, full and free action of the skin. According to my way of thinking and reasoning, the patient was placed under the most favorable conditions for fighting the disease. Generally large quantities of fecal matter were voided, and the pores were thoroughly opened. Next, the rest of the treatment was in order. It was of the simplest. A teaspoonful of the acid phosphate in a half-tumbler of water every hour or two, day and night, for the first twenty-four hours. It never caused nausea. I continued it for two or three days, according to temperature and symptoms. The bowels continue to act freely—bilious motions. Later they became very dark under the acid. Previously I had used sinapisms and a lot of things recommended by the books, and those supposed to be experienced in treating the disease. The sinapisms were placed over the stomach to try and check the distressing vomiting, at times they were beneficial; again, useless. Diet in these cases is a matter of very small importance. They are too busy with the disease. I fail to recall a single case where food of any kind was asked for. The highly irritable stomach must be remembered. Iced milk and beef broth in very small quantities at frequent intervals, *if the stomach tolerates them*. Iced lemonade and pure soda-water. Small pieces of ice allowed to dissolve in the mouth. I gave champagne a fair trial and abandoned it. I am satisfied that the purely acid treatment is ample. The simpler the treatment the better. The quinine and sulphate of soda mixture, vapor baths, *à la* Wilson, and the acid meets all requirements. I abandoned the old-time treatment. As I have already informed you, I had three recoveries, one after the other, all in infected premises where the previously attacked had died. These recoveries were in the fall of 1884. Early in the spring of 1885—March—I left for my annual holiday, visiting Nicaragua, when I returned to the Isthmus, to leave it, April 25th, for New York City.

Three swallows do not make a summer, nor do I claim that three successive recoveries are everything, but as nearly all attacked died, I do earnestly claim that three successive cases getting well furnish food for thought. Personally I am satisfied that by persistently acidulating the life-currents they ceased to be blood-heat culture fluids for the germs of yellow fever. I say germs. The following facts will I believe strengthen my claim that three successive recoveries were absolutely unheard of at Panama. A few words regarding the dying from yellow fever thereaway. I can recall twenty-seven admissions to the yellow fever ward of the Canal Hospitals, Panama, with but a single recovery. My brother, the late Dr. George W. Nelson, then Resident Surgeon, furnished me with the figures. Of 42 cases sent to the Charity Hospital, Panama, during the epidemic of 1880, when I had the disease, not a single recovery. As a concluding statement, I could amplify them to any extent—the Dingler Expedition and its experience will be ample. Mr. and Mrs. Dingler, accompanied by Mr. and Miss Dingler and a party of Canal Engineers, all told, a party of thirty-three, arrived at Colon in October, 1883, Mr. Dingler being the new Director-General of the Canal Works. Within six weeks of landing Count de Cuerno and Mr. Zimmerman were dead—specific yellow fever. Within fifteen months of the landing of that party of thirty-three, fourteen had had yellow fever and but one recovered (Mr. Dingler losing his wife, son and daughter), he was a patient of mine, a Canal Officer, and had been on the Isthmus previously. His regular life no doubt was the factor that saved him. Contrast three successive recoveries with the above—my cases were specific yellow fever.

As previously intimated, yellow fever spares none. While it is quite true that total abstainers have been swept away by it, it is equally true that even in the severest cases, they have recovered, where the moderate drinker was lost from the start. Time and again my own experience has confirmed this. The regular life, particularly within the tropics, is its own reward. In Ziemssen's Encyclopædia, Vol. 11, in the article on yellow fever much valuable information will be found on this subject, the value of total abstinence—"Panama in 1855," Harper Bros., New York. Dr. Otis' work, "The Handbook of the Panama Railway," 1860, Harper Bros. Dr. L. Girerd's work on Panama, published in 1883, in French, in Paris, all contain much information regarding that land of pestilence and death, as well as "Five Years in Panama," 1889, Belford, Clark & Co., New York.

In reference to the inestimable benefits of total abstinence within the tropics, it simply confirms the opinion of a valued friend at Panama. The Consul-General of the United States, who, when asked, "How do you live in the tropics?" wittily

replied, "It all depends on the *liver*," So it does. An alcoholic liver in yellow fever means death.

The time allowed for the reading of this paper necessitates my leaving out much that I should like to discuss. I must ignore the interesting history of the disease and hasten on.

A few words or points on the after-treatment. The treatment during convalescence calls for constant watchfulness. It is here, that malarial symptoms crop up, in the cases of those who had been at Panama a few months. Dr. L. Girerd examined the blood of hundreds on arrival, and found it normal, in no case showing the malarial bacillus. After the first month he re-examined scores of them; the blood of all showed it, simply confirming the statements to be found in Dr. 'Tomes' work, "Panama in 1855," statement amplified in Dr. L. Girerd's work.

To return to the stage of convalescence, I have known a beefsteak to cause death on the tenth day. During convalescence such patients are simply ravenous. Well do I recall my own intense hunger. Slops are in order, fluid food, given at short intervals, not to overload the stomach. Its irritability lasts for weeks and weeks. Bathing, a thorough washing of the patient's body and hair daily in a weak carbolic bath, the thorough disinfection of the patient's effects and room.

The majority of cases were fatal on or before the fifth day, closing with the black vomit, suppression of the urine, etc. In such patients it was fever of a single "access," or paroxysm. Other cases passed through the "period of calm," and died in the third stage, or that of "secondary fever," from the sixth to the ninth day. Cases of typhoid character were rare. I saw but one, being that of my friend Dr. Arthur Gore, now in San Francisco, California.

The sequelae: boils, pimples, parotid swellings, and intermittent fever, jaundice—I was of a rich canary color. It lasted a whole month. People were never curious about it or anxious to ask me questions—not any.

Now for a very brief reference to *post-mortem* appearances. My small experience under this heading simply confirms what an old and clear-headed American writer has stated, "Yellow fever has no pathology." I refer to Dr. Grenville Dowell, whose little *brochure* contains a mine of information, or what the great French Undertaker, M. DeLesseps, calls "an arsenal of facts."

The *post-mortem* findings are so variable in patients cut off by the same symptoms, that no reliance can be placed upon them. I deem it a blood disease, pure and simple, and, if my view is accepted, the absence of any marked pathological change, save in the blood itself, cannot cause surprise.

The liver: It presents a variety of conditions. I have found it fatty; again, fatty on section,

showing an immense quantity of oil globules; again, perfectly normal in size and color. The chamois-colored liver is supposed to be the characteristic liver. I never saw but one, and that was the only one in nearly one hundred autopsies made at the Canal Hospitals, Panama, by Dr. S. Didier, a gentleman profoundly versed in yellow fever. He was born in one of its habitats, the island of Martinique, French West Indies.

The kidneys: Nothing constant. I met them large and small; again, perfectly normal to the eye.

The stomach: This organ presents signs of acute inflammation. Generally its coats were thickened; it contained more or less black vomit; I saw nearly a pint in one case; its inner surface showing innumerable pink points or *foci* of congestion, and small deposits of blood. Dr. Castellanos, a physician of the Charity Hospital, Panama, a Spaniard, told me that it was the only constant condition found by him, and he, while living in Cuba, had made nearly 150 autopsies.

The brain I have never examined. Dr. L. Didier found nothing worthy of remark in his large experience. Nothing.

The blood: I have always found it in a perfectly fluid condition. Remember the destruction of the blood and the great amount of albumen eliminated by the kidneys. Its specific gravity taken by me two hours after death, was nearly normal. To this fluid we must direct our whole attention. To repeat, I consider it a blood disease, pure and simple, and have held this view since 1884. Death in these cases is due to a true necremia. If this view, which I believe is peculiar to myself, be proven, we have an explanation of a majority of the symptoms of yellow fever, and as already stated, it explains the absence of any characteristic pathological changes, save in the blood.

The brain symptoms are due purely and simply to the destruction of our oxygen-carriers, the red corpuscles. The great Virchow attributes loss of consciousness to their failure to carry oxygen. By rendering the blood uninhabitable to the germs that prey upon and destroy the corpuscles, we triumph. Much remains to be explained about yellow fever. Many honest and patient toilers are at work on this great problem. I believe that with the discovery of the specific germ by Dr. Domingos Freire, of Rio de Janeiro, Brazil, by Dr. L. Girerd, at Panama, and its discovery by Dr. Carlos Findlay in Havana—to his and the work of his friend Dr. Delgado, of that city—add to this, our knowledge of the truly wonderful strides made by these gentlemen in their bacteriological studies and inoculations—to the above, by acidulating the blood, as I have done, where it has invaded the system—with such factors, the future seems full of hope to me. May it prove so. Having digressed, I must go back to the *post mortem* findings

The bladder: Generally a few drachms of highly albuminous urine were found. Remember the suppression.

Black vomit has a peculiar odor, and is slightly acid to the taste. To clear up a vexed point in my mind, I collected some in one of my cases and tasted it. It required a little courage, but I was in earnest and working for results. I may state *inter alia* that it will never compete favorably with other beverages. The "vomit," on settling, deposits coffee-ground "particles," the fluid above being the color of weak black tea. Black vomit is not bilious vomit. I tasted it to clear up this very point. Black vomit as a symptom is of grave import.

It indicates blood changes—the beginning of the necremia. While at Panama I sent my friends specimens of my late patients. My rooms were miniature graveyards. Some "black vomit" sent to my old classmate, Dr. Wm. Osler, then Professor of Clinical Medicine in the University of Pennsylvania, with other materials furnished *pabulum* for a lecture on vomited matters. To-day, he is Professor of Practice of Medicine in the Johns Hopkins University, Baltimore, Md., and Physician-in-Chief to the magnificent hospital of the same name.

To recapitulate: Now that Drs. Freire, Girerd, Findlay and Delgado have found the same germ, Dr. Domingos Freire being the first investigator, and its discoverer, to him the honor and credit are due. He caused others to work. Now that this has been accomplished, I firmly believe a new era is at hand, and that soon, this constant reproach to our profession, and much vaunted modern civilization, the sway of yellow fever, is about to receive its *coup de grace*. Inoculations will protect man against this awful disease as vaccine does against small-pox. Dr. L. Girerd proved his good faith in such a vaccine, if the term is permissible, by making attenuated cultures of the microbes of specific yellow fever, and by inoculating himself and without carrying it to its full protective influence, he allowed himself to be bitten by mosquitos (Dr. Carlos Findlay's discovery) that had been feeding on a man in the yellow fever ward of the Canal Hospital, a case of specific yellow fever, the fifth day, the mosquitos were disturbed and allowed to bite him. The result was a mild yellow fever. I translated his report, and it was published in the *Canada Medical Record*, Montreal, in the fall of 1886, together with an editorial.

With inoculations to protect and prevent, and the purely acid treatment where the germs have invaded the system—with these, and a strictly scientific quarantine, *à la* Dr. Joseph Holt, our profession can save the lives of hundreds of thousands in the future, who but for such means would die like rotten sheep. The acid, I believe, is a germicide in these cases. I like the

term and make no apology for using it. Intermittent fever, as we well know, thanks to the crucial work of Leveran, Girerd and Osler, has its *bacillus malarie*; quinine is its germicide.

When these things are thoroughly understood and put in practice, travel in the tropics will be divested of its terrors. People ere visiting them for business or pleasure will be inoculated, and with quarantines, *à la* Dr. Joseph Holt, the commerce of nations will be almost free and untrammelled.

Here, gentlemen, I must say farewell. I have to thank you for your kind attention and patience. In the near future, I trust that you will recall these statements made in the presence of the Members of the State Medical Society of Arkansas, on this, the 28th of May, 1889.

Articles extensively quoted in preceding, from author's papers as under:

## CASES OF INFANTILE HEMIPLEGIA.

BY WILLIAM L. WORCESTER, M.D.,

ASSISTANT PHYSICIAN TO THE ARKANSAS STATE LUNATIC ASYLUM, LITTLE ROCK.

The following fourteen cases of infantile hemiplegia have come under my observation in this institution, all but one being under treatment at the same time, in a total population of 479 patients. They exemplify most of the symptoms usually found in such cases, and are, perhaps, of sufficient interest to be put on record, although I cannot lay claim to any original discoveries in connection with them. The histories furnished at the admission of the patients are, I regret to say, so imperfect as to be worthless for the purposes of this article.

*Case 1.*—Margaret B., aged 30. Said to have become paralyzed at the age of eight months. The left side of the face is smaller than the right, and less strongly innervated. Left arm shorter and smaller than right; good movement of elbow,

shoulder and wrist joints; imperfect abduction of fingers, movements of hand somewhat awkward and weak. Has occasional sudden choreiform twitchings of arm and hand. Left lower extremity not shortened and but slightly smaller than its fellow. She limps and drags the toe slightly in walking. Knee-jerk much exaggerated in left leg. She has frequent and severe epileptic convulsions, which begin by extension of the left hand and arm and conjugate deviation of head and eyes to left, before consciousness is lost. Frequency of convulsions much diminished by use of bromides. Her skin presents a deep bluish discoloration, doubtless from the effects of nitrate of silver.

*Case 2.*—Ellen B., aged 28. Says she became paralyzed in infancy. Left side of face better innervated than right. Right elbow and wrist flexed nearly at a right angle and capable of but little movement; fingers extended. All parts of the extremity shorter and smaller than that of its fellow. Hand practically useless. No decided difference in dimensions or mobility of lower extremities. Knee-jerks somewhat more active than usual on both sides. She has occasional general convulsions, which she says begin with cramping in the right arm.

*Case 3.*—Ellen B., aged 29. Says the right side has always been paralyzed. Face unaffected. Right upper extremity shorter and smaller than left; forearm pronated; wrist strongly flexed; hand closed with thumb outside. She cannot lift the arm to the level of the shoulder; flexion and extension of elbow-joint all good but supination is imperfect; can move the wrist but slightly. There are constant slow, slight, involuntary movements of the wrist and fingers. The right lower extremity is proportionately more atrophied than the upper; it is shortened three-fourths of an inch, and the thigh is three inches and the calf two inches smaller than its fellow. It is partially flexed at hip and knee, and there is marked talipes equino-varus. The foot is dragged in walking. There are involuntary movements of the ankle and toes, similar to those of the upper extremity. Has general convulsions, not very frequent. Order in which muscles are affected unascertained.

*Case 4.*—Georgiana G., aged 15. Left side of face slightly smaller than right; innervation not sensibly different. Left eye deviates upward and outward. Arms of equal length; left slightly smaller. Extension of left elbow and wrist incomplete. Both little fingers somewhat contracted. She has pretty fair use of the left hand. Left calf is one-half inch larger than right, thighs equal; no shortening. Left ankle cannot be (dorsally) flexed; attempts to do so result in adduction. She is not known to have had any convulsions since her admission, in 1887, until October, 1888, when she had one. On January 15, 1889,

she had four severe convulsions, and since then has dragged the left foot, which previously had not been very noticeably lame.

*Case 5.*—Mary J., aged 42. Right side of face smaller than left; tongue deviates to right when protruded; nystagmus; convergent squint of left eye. Elbow slightly flexed; forearm pronated. Cannot raise arm above the level of shoulder, fully extend elbow, or hyper-extend wrist. Can execute all the ordinary movements of the fingers, but only by making the same movements with the left hand. The right extremity is smaller than the left in all its parts and dimensions.

The right lower extremity is also much smaller than the left, especially the calf, which only measures 9 $\frac{3}{8}$  inches against 12 $\frac{1}{4}$  on the left side. The hip and knee-joints are somewhat limited in movement, and there is complete talipes varus, the patient walking on the outside of the foot. Knee-jerk exaggerated, right side. She says that the paralysis is congenital. Has epileptic convulsions, which are stated to have begun at the age of 37.

*Case 6.*—Kate T., aged 27. Says her paralysis is due to an injury to the head from a fall at the age of one year. No scar or evidence of fracture can be found. Left side of face smaller than the right, but seems equally well innervated. The left upper extremity is shorter and smaller than the right. Movements of elbow and wrist are free, but those of the shoulder are limited, and the fingers cannot be completely closed or abducted. The left lower extremity is shorter and smaller than the right; movements good, except that dorsal flexion of the ankle is imperfect; knee-jerk exaggerated. Convulsions pretty frequent; she says she first has a "nervous" feeling in her head, and then tremor in the left hand and foot, which sometimes passes off without loss of consciousness.

*Case 7.*—Georgiana H., aged 15. Says paralysis dates from an illness at two years of age. Left side of face smaller than right; innervation equal. Arms equal in size; movements in all joints free, but she is awkward and clumsy in the use of the left hand, and there are constant, slow, irregular movements of the fingers, especially marked when the hand is open. There is slight talipes equino-varus of the left foot, and the toe is dragged in walking. Has frequent epileptic convulsions, beginning with cramp in the left arm and hand. The bromides, which hold the convulsions in check to some extent, seem to aggravate the spastic character of the gait.

*Case 8.*—Martha T., aged 22. Left side of face smaller than right; no marked difference in innervation. The left arm is one-fourth inch smaller than the right; the fore-arm, on the contrary, one-half inch larger. The forearm is pronated, and the wrist flexed to a right angle, with little mobility. Voluntary movements of fingers very

imperfect. There are constant slow involuntary movements of the thumb and fingers, which probably account for the hypertrophy of the forearm. There is no atrophy of the lower extremity, and no impairment of movement except in the ankle, which cannot be flexed beyond a right angle. She has frequent attacks of convulsions, which begin by strong flexion of the left hand and forearm.

*Case 9.*—Louisa M., aged 27. Says she became paralyzed at the age of three months. Left side of face smaller than right, no paralysis. Left arm shorter and smaller than right; cannot be lifted above a right angle at the shoulder. Movements of elbow good; wrist cannot be hyper-extended; closure of hand imperfect. Right lower extremity longer and larger than left. Dorsal flexion of left ankle imperfect; knee-jerk exaggerated on left side. Feels premonitions of convulsions in her head, and has tremor of left hand and foot before losing consciousness.

*Case 10.*—Thomas M., aged 15. Left side of face smaller than right; innervation equal. Upper extremities equal in size. The fingers of the left hand tend to take the position characteristic of paralysis of the interossei, and the use of the hand is imperfect. When he opens or closes the left hand slight movements of the same character take place in the right. The left lower extremity is one-half inch shorter than the right; the knee cannot be completely extended, and there is slight talipes equino-varus. When he stands the toes are strongly flexed. When the weight is taken from the foot they are in constant, slow movement. He has frequent convulsions, beginning in the left upper extremity.

*Case 11.*—Riley T., aged 29. Says he became paralyzed in infancy. Right side of face smaller than left. Right arm not materially smaller than left; movement of fingers clumsy and imperfect. The arm jerks when he attempts voluntary movements with it, and there are slight movements of athetosis in the fingers. The right calf is three-eighths inch smaller than the left, and the right knee-jerk is exaggerated. There is tendency to hyper-extension of toes. He walks without noticeable limp. His convulsions, which are very frequent and severe, occur suddenly and without warning; he drops as if shot.

*Case 12.*—Edward H., aged 18. Says a rail fell on his head when he was two years old; attributes convulsions and paralysis to the injury. Has a depression in the frontal bone, about one inch from median line, three-fourths of an inch in diameter, and extending a little beyond the coronal suture. The left side of the face is slightly smaller than the right. The left arm is not shortened, but is slightly smaller than its fellow; the wrist cannot be fully hyper-extended, and the movements of the fingers are imperfect. When the hand is at rest there are constant slight move-

ments of the fingers, most marked in thumb and forefinger. Left lower extremity slightly smaller than right; foot cannot be extended without adduction, nor flexed (dorsally) beyond a right angle. There are constant slow movements of flexion, extension, adduction and abduction in the toes; the great toe is often raised almost to a vertical position. Says he has warnings of his convulsions, which are frequent, but cannot describe them. His attendant says they begin with contraction of the left arm and hand.

*Case 13.*—William McV., aged 28. Origin of paralysis unknown. Said to have been epileptic for seventeen years. There is no very marked asymmetry of the face, but innervation is rather better on the left side than the right. Slight divergent strabismus of right eye. There is no material difference in the length of the upper extremities. The left biceps measures  $2\frac{1}{4}$  inches and the left forearm 2 inches more in circumference than the right. The right elbow and wrist cannot be fully extended; the hand can only be incompletely closed, and is of little use. Lower extremities of equal length, but the right thigh is  $1\frac{1}{2}$  and the calf  $1\frac{1}{4}$  inches smaller than the left. Cannot flex (dorsally) right ankle; foot deviates inward slightly when extended. Knee and hip slightly flexed. Patient walks with a limp, but does not drag foot. No involuntary movements of either extremity at time of examination. He has rather infrequent convulsions, which he says always begin with cramping in right hand and arm before he loses consciousness.

*Case 14.*—Susan B., aged 42. Said to have become paralyzed at the age of 7 months, and to have suffered from convulsions ever since. The face is much distorted by cicatrices from an extensive burn. The right upper extremity is 1 inch shorter than the left, but the circumference of the arms is equal, and the right forearm is only  $\frac{1}{4}$  inch smaller than the left. There is free mobility of all the joints, but voluntary movements are clumsy and feeble, and there are almost constant irregular movements of the thumb and fingers more extensive than in any other of the cases. The right foot is in the position of equino-varus; the knee- and hip-joints are slightly flexed and cannot be fully extended, and locomotion is greatly impeded in consequence. There are athetoid movements of the toes. The patient has been received since this paper was begun, and there has not been, thus far, opportunity to observe the mode of onset of the convulsions. Mentally she is almost idiotic.

#### ANALYSIS OF THE FOREGOING CASES.

*Sex.*—Four of the patients are males and ten females. Most observers have found girls were more frequently affected than boys, but so great a predominance of one sex must probably be considered fortuitous. Gowers' states that of 80

cases 35 were boys and 45 girls. Of 120 reported by Osler<sup>2</sup> 63 were girls.

*Side Affected.*—In 8 cases the left side was affected, in 6 the right. Gowers<sup>3</sup> says he found the left side paralyzed in 37 out of 80 cases, the left in 33, which leaves 10 unaccounted for. He considers that the two sides are affected with about equal frequency.

*Atrophy.*—It is, of course, the rule in hemiplegia that there is some shrinking of the paralyzed muscles. It has, however, frequently been observed in infantile cases that the bones of the affected side are less developed than those of the sound side. In my cases the bones of the face were as frequently affected as those of the extremities, being distinctly smaller on the paralyzed side in 10 cases. This is the more remarkable as in most of these cases there was no very noticeable difference in the activity of the muscles, though I found in several of them that the patients could not close the eye on the affected side while holding the other open. There was shortening of one or both paralyzed extremities in 10 cases.

*Extremity Principally Affected.*—In most of my cases the paralysis follows the general rule in affecting the upper more than the lower extremity. In case 2 the power and mobility of the leg are very slightly impaired, and the case should perhaps be considered one of brachial monoplegia. In cases 5, 10, and 14, on the contrary, the paralysis, atrophy and contracture are all in excess in the lower extremity, and in cases 3 and 4 it can hardly be said that either predominates.

*Athetosis and Chorea.*—In three cases there were slow, involuntary, irregular movements (athetosis) of the fingers, in one similar movements of the toes, and in three both fingers and toes were involved. In one case there were sudden, irregular movements of the paralyzed hand, which were not, however, very extensive or violent. In one case the muscles of the affected forearm were more developed than those of the sound side—doubtless on account of their continual activity. Osler<sup>4</sup> only found athetosis in six of his cases.

*Convulsions.*—All of these patients are epileptics. The frequency with which cases of infantile hemiplegia are afflicted with epilepsy is in striking contrast with its comparative rarity in connection with hemiplegia occurring in adult life. The frequency with which this complication occurs has varied very greatly in different collections of reported cases, and no conclusions on this head can be drawn from these cases, as it is probable that the mental symptoms which occasioned their committal to this institution were less the direct effect of the cerebral lesions than of

the resulting epilepsy. All are subjects of the *grand mal*, but several of them have attacks, at times, confined to the paralyzed side, without loss of consciousness. In eight of the cases the convulsions begin with spasm of the paralyzed side; two fall suddenly and pass at once into general convulsions, and in four I have not been able to ascertain the mode of onset.

*Strabismus.*—Three of the fourteen patients have strabismus. The proportion seems large if it is merely a coincidence, and none of the patients present errors of refraction which seem to account for the state of the ocular muscles. Two of them (cases 4 and 5) were examined by Dr. T. E. Murrell, of this city. He found a considerable degree of hyperopia in the former case—a condition which is one of the principal causes of convergent squint, but would not seem to throw any light on the condition present. The other case was found to be emmetropic. In case 13, also, the only anomaly of refraction discovered is a moderate degree of astigmatism. On the other hand, the connection of the strabismus with the cerebral lesion is not easily made out. The muscles of the eye are not usually affected in paralysis from that cause, and in two of the three cases the eye affected is on the sound side.

*Mental Symptoms.*—It is probably impossible to say how much of the mental impairment noticeable in these cases is the direct effect of the damage to the brain and how much to the epilepsy from which all the patients suffer. Imbecility, amounting in some of the cases to almost complete idiocy, is a marked feature of all, and most of them manifest the selfish, irritable and quarrelsome disposition so common in epilepsy. The religious sentimentality so often observed in that disease is absent, and delusions are a prominent symptom in only one case.

I have not had, either here or elsewhere, an opportunity to make post-mortem examinations in cases of this kind. A full discussion of what is known in regard to their pathological anatomy can be found in the exhaustive paper of Dr. Osler, already referred to.

THE American Association of Obstetricians and Gynecologists will hold its next annual meeting at the Burnet House, Cincinnati, O., in the rooms lately occupied by the Military Order of the Loyal Legion, on Tuesday, Wednesday, and Thursday, September, 17, 18 and 19, 1889. No formal invitations will be issued to non-members, but the Association extends a cordial invitation to such members of the profession wherever resident as may feel interested, to attend the meeting and participate in the proceedings. The papers and discussions will embrace subjects pertaining to obstetrics, gynecology and abdominal surgery.

## MEDICAL PROGRESS.

**MIXED INFECTION IN GONORRHOEA.**—Analagous to the definite sequelæ which are observed in various affections and which, as proved by bacteriological investigations, are caused by the entrance of various microorganisms into the tissues at the same time, are the various complications of gonorrhœa, such as inflammation of the erectile tissues, peri-urethral abscess, bubo, prostatitis, vesical catarrh, gonorrhœal rheumatism, peri- and parametritis, inflammation of the Fallopian tubes, Bartholinitis and endocarditis. These are mixed infections produced by the gonococcus together with other pathogenic microorganisms. The author adduces, in substantiation of this statement, the assertion of Bumm that the gonococci develop only in cylindrical epithelium, or in tissues which, in their histological structure, are closely related to cylindrical epithelium, and the fact, as experimentally demonstrated by Rinecker, that when gonococci are injected into the connective tissues they disappear without leaving a trace behind them. Throughout the entire course of gonorrhœa, however, opportunity is afforded for the entrance of other pathogenic organisms through the ulcerations of the mucous membrane. These find, in the profuse secretion present, the very best conditions for their propagation and further advance into the lymph and blood channels, whereby the complications of gonorrhœa arise. Were it not that gonorrhœa is a purely local affection of a mucous membrane provided with cylindrical epithelium, these complications would be observed very much oftener. The relative frequency of these complications, however, is explained by the readiness with which microorganisms other than those of the gonorrhœal variety find their way from the diseased mucous membrane of the genitalia into the tissues and lymph channels.

Bumm has discovered a yellowish-white diplococcus which, as well as the staphylococcus aureus and albus (which are often found in gonorrhœal complications together with the gonococcus) may easily be confused with the gonococcus and thus mislead one into the belief that the pathological process is a uniform one, whereas, in point of fact, it is a question of mixed infection.—GERHEIM, *Centralblatt für Gynäkologie*.

**TREATMENT OF ABSCESS OF THE LIVER.** By MON. CHAUVEL.<sup>1</sup>—I have had opportunity to observe four cases of abscess of the liver in military hospitals. These abscesses occurred in soldiers returning from Tonquin and Algiers, all of whom were markedly anæmic as the result of dysentery. The air of their native country had at first ameliorated their condition, but soon the attacks of

dysentery and diarrhœa recurred, with febrile exacerbations, quotidian fever, intercostal pains, either vague or localized in the hepatic region, pain about the scapula, and absolute anorexia. Abscess of the liver was diagnosticated, the diagnosis being verified by means of an exploratory puncture. The development of these various symptoms was much more sudden in the cases of the soldiers from Tonquin than in the single instance of the one from Africa.

In two of the cases the abscess occupied the right lobe, in the other two the left lobe; these latter cases terminated fatally.

Incision with the bistoury presented no serious difficulties; it corresponded with the seat of swelling, at which point the puncture had been made with the trocar.

The following are the conclusions derived from a study of these four cases:

1. Immediate, direct incision of abscess of the liver by means of the bistoury presents no danger as regards the development of peritonitis, if it be made antiseptically.

2. The opening should be large and lead directly into the abscess cavity. On account of the retraction of the liver after the evacuation of the fluid, it is well to make it as high up as possible; if it retract upon the collapse of the ribs, resection of the latter may be indicated.

3. It is useless and perhaps dangerous to suture the liver to the edges of the parietal wound.

4. The large opening should be made early, and the exploratory punctures are clearly indicated as soon as there is a suspicion of pus.

5. It is almost always impossible to recognize the existence of multiple foci with sufficient accuracy to reject the possible intervention of an accessible tumor. In these perplexing cases the large incision in the principal focus causes the disappearance of one of the sources of fever; it favors the opening of the secondary foci into the principal cavity, already emptied, and if it does not arrest the progress of the affection at least it exerts no unfavorable influence upon its course.

6. Abscesses of the left lobe appear to be the more serious, a fact which may, perhaps, be explained by the possibility of a pericarditis by extension, and by the probability of other collections of pus in the large right lobe.—*Le Bulletin Médical*.

**RUPTURE OF THE LIVER WITH A LARGE PERITONEAL EFFUSION OF BLOOD SIMULATING A RIGHT HÆMOTHORAX.**—FÉVRIER and CHAVIER, (*Centralblatt für Gyn.*, January 19, 1889). A soldier was violently hurled from a falling horse in such a manner as to strike a tree with the left side of the thorax. The horse fell so heavily as to be instantly killed. The man was rendered unconscious; when first seen his face was pale, there was marked dyspnoea, a small pulse and

<sup>1</sup> Read in the Académie de Médecine, Paris, May 7, 1884.

grating of the teeth. He had passed urine. Sensibility was normal. There was a fracture of the middle portion of the 3d, 4th and 5th ribs. There was no superficial injury of the abdomen apparent and no where sensitiveness upon pressure. The liver dulness was normal, the abdomen soft. There was an area of dulness two fingers breadth in extent in the postero-inferior part of the right thorax. Respiratory movements were feeble. Rupture of the lung from indirect force, and a consequent hæmorrhage, was diagnosed. During the next few days the bowels and bladder acted normally; the belly was soft and painless; the area of dulness on the right side gradually increased until it reached the angle of the scapula. The right inferior portion of the thorax expanded, dyspnoea and bodily temperature increased, and the patient died on the fourth day after the injury. The liver dulness had always remained normal. An autopsy revealed little worthy of note in the left lung; in the right pleural cavity there was about one-half a litre of fluid; the diaphragm was pushed up so high that the pleural cavity was encroached upon to one-half its extent. There was a great deal of blood in the abdomen. In the right lobe of the liver, 2 cm. from the suspensory ligament, there was a rupture through the entire thickness of the organ, 13 cm. in length. At the posterior border of this rupture there was a cavity of large size filled with fragments of liver substance. It may easily be understood why the above described symptoms gave the impression of a right-sided hæmorrhage.

ON CREOLINE IN DYSENTERY.—N. P. SOSSOWSKY (*Pract.*, No. 14, 1889) used in sixteen cases of dysentery clysters of a solution of  $\frac{1}{2}$  per cent. of creoline. The clyster (from 2 to 3 and even 3½ litres) was generally given twice a day, sometimes three and even four times. No disagreeable secondary symptoms. The patients did not complain of either smarting or abdominal pain. The results obtained were as follows: In two cases the disease was broken up after two injections; in nine cases the bloody stools disappeared on the third day, in two on the fifth, in one on the sixth, and in another on the ninth. In the last case the appearance of putrid matter in the stools was not checked, but the patient recovered nevertheless. Not one of these patients died, although there were a great many cases with fatal termination reported in the city. From these observations the author draws the following conclusions:

1. Clysters of a  $\frac{1}{2}$  per cent. solution of creoline possess antiseptic qualities and seem to be less dangerous and toxic than the clysters of sublimate or phenol.
2. Clysters of creoline check the blood without irritating the intestinal channels.
3. Cases acute from the beginning, with frequent tenesmus and copious bloody stools, take

a more favorable course and are cured more rapidly than cases insidious at the beginning, characterized by catarrhal stools.

4. In cases where the creoline clysters do not stop the development of the intestinal catarrh, clysters of tepid water and subsequently of a solution of acetate of lead  $\frac{1}{2}$  per cent., or of tannin of 1-2 per cent., should be prescribed; at the same time a decoction of the bark of quinquina should be taken internally with sulphate of soda.

The author has successfully used the same treatment in two children, one 11 and the other 9 months old. Dr. Kolokoloff has also prescribed creoline clysters (1 per cent.) in twelve cases of dysentery; all the patients recovered without showing at any time alarming secondary symptoms.—*Les Nouveaux Remèdes*, No. 11, 1889.

THE DIAGNOSTIC TAMPON AND ITS VALUE IN THE RECOGNITION OF CHRONIC ENDOMETRITIS.—B. S. SCHULTZE (*Centralbl. für Gyn.*, Mar. 11, 1889). In 1880 Schultze described a method which he had been employing for several years as furnishing a means for the early diagnosis of endometritis. He now reaffirms all that he then said of the value of his method, and expresses much surprise that it has not attracted a greater amount of attention. The diagnostic tampon is made of absorbent cotton soaked in a 20-25 per cent. solution of tannin in glycerine. This, after careful cleansing of the vagina, is pressed firmly against the cervix so as to fully cover the os and portio vaginalis. The glycerine solution absorbs water from the surrounding tissues and allows it to escape, together with the watery part of the secretions, the remainder of which is arrested by the cotton. After 24 or 48 hours the tampon is removed, whereupon, if the uterus be healthy, a lump of vitreous cervical mucus is found. If, on the other hand, any portion of the mucous membrane above the tampon is secreting pus, the secretion will be found on the tampon. It is not the quantity and watery character of the secretion that proves the presence of endometritis, but the pus therein contained. The quantity of the secretion is often so moderate that patients do not complain of it, and indeed if the cervix and vagina are not affected a very considerable degree of endometritis may occasion so small a discharge that patients assure their physician in good faith that there is none.

Schultze claims that too much stress is laid upon abnormal discharge of blood as the diagnostic feature of endometritis, and that there is a much larger class of cases in which hæmorrhage has not appeared or does not tend to appear, and that these very cases of beginning endometritis are easily recognized by means of his tampon.

ON COMPENSATORY HYPERTROPHY AND THE PHYSIOLOGICAL GROWTH OF THE KIDNEY.—TH.

ECKARD reports, in *Virchow's Archiv*, No. 2, vol. cxiv, the result of careful comparative measuring and counting of the constituents of eight normal kidneys from different ages (1 day to 48 years), as follows:

1. With the cessation of embryonic growth new glomeruli no longer develop. The physiological growth of the kidney as far as the glomeruli are concerned is, therefore, purely hypertrophic. 2. The tubuli contorti increase considerably during the first years of the life of the individual, in thickness as well as in length. Subsequently growth is limited to increase in length, but the author is unable to decide whether it consists in hyperplasia or in hypertrophy of the epithelium. The examination of the intact hypertrophic kidneys in three interesting cases of congenital defect in the kidney showed that the compensatory hypertrophy of a kidney as result of an innate defect is caused primarily by a hyperplasia (an augmentation) of the glomeruli as well as of the urine channels, but that at the same time a hypertrophy of the Malpighian bodies and of the tubuli contorti is going on. Compensatory hypertrophy of a kidney as result of an acquired defect, however, is always caused by hypertrophy of its constituents.—*Centralblatt für Klinische Medizin*, No. 22, 1889.

CONTRIBUTION TO ELECTROTHERAPY IN GYN-ECOLOGY.—ORTHMANN reports the results obtained in 95 cases treated in Martin's clinic in Berlin. Among these, most of which were chronic cases of inflammation of the uterus and the surrounding parts, there were 36 cases of perimetritis; in one case there was a very favorable result, in 24 cases marked improvement, and in the remaining 11 no appreciable change. In cases where there was great sensitiveness, the faradic current or the positive pole of the galvanic current was employed; in cases of moderate sensitiveness the negative pole; this was introduced in the form of a ball electrode into the posterior cul-de-sac, while a flat electrode applied to the abdomen was made the other pole. The current varied in strength between 50 and 100 ma. The number of sances varied from six to eighteen, the length of each sance averaged five minutes. At most there were two sances per week.

In similar manner twelve cases of parametritis were treated; in eight of these there was improvement, in the others none. In five cases of para- and perimetritis, exudate of greater or less extent, there was improvement in three, no change in one, and retrogression in the last.

The most favorable results were obtained in the treatment of severe dysmenorrhœa and amenorrhœa. In twenty-six cases of dysmenorrhœa dependent upon metritis, endometritis, retroflexion of the uterus, and stenosis of the cervical canal, six were cured, while the others were mark-

edly improved. In like manner of four cases of amenorrhœa three were cured, while the fourth remains under treatment. In the treatment of dysmenorrhœa and amenorrhœa the negative electrode was used especially, being introduced into the uterus while a current of from 50–75 ma. was employed.

As a result of these experiments, the writer believes that additional information is required, especially as regards the treatment of dysmenorrhœa and amenorrhœa.—*Centralbl. für Gyn.*

THE INJECTION OF COCAINE IN SPASTIC CONTRACTION OF THE JOINTS.—In primary inflammatory contraction of the joints, that is, in those cases where a contraction of the joint results from an inflammatory irritation or from an inflammation of any of the constituents of the joint, LORENZ recommends (*Wiener klin. Wochenschrift*, No. 9, 1889) as the simplest and surest treatment for the removal of the muscle-spasm, injections of cocaine into the respective space of the joint. He uses for this purpose a common Pravaz syringe with a somewhat longer needle, and injects with antiseptic precaution one-half or a whole of a syringe of a 10 per cent. solution of cocaine into the joint. Immediately after the injection the pain disappears, and a few minutes later the joint may be put into the correct position and fixed, or extended. This mode of treatment is especially recommended for the correction of spastic club-foot. Children bear cocaine very well; in adults more caution is necessary, a few centigr. often being sufficient to produce the desired effect. In Albert's clinic a general narcosis is no longer used for primary inflammatory contractions.—*Centralblatt für Chirurgie*, No. 23, 1889.

SULPHATE OF ESERINE IN CHOREA.—REISS (*Pharm. Journ. and Transact.*, No. 2, March, 1889) recommends subcutaneous injections of sulphate of eserine for chorea; dose 0.001 gr., twice daily. He claims to have effected a cure in many cases after five or six days of treatment, although in acute cases of chorea in adults success was not so very brilliant. He obtained also satisfactory results with this drug in tetanus, paralysis agitans, spinal sclerosis, and in one case of hysteria in a man, accompanied by extreme excitement and a remarkable exaggeration of the reflex movements.—*Journal de Médecine de Paris*, No. 21, 1889.

ON INFANTILE LEUCÆMIA.—PROF. JAKSCH lost a patient some time ago, a little boy 20 months old who was suffering from genuine lymphatic leucæmia. This disease is extremely rare at this age, and consequently this case is quite interesting. The diagnosis was verified by the autopsy, M. Jaksch finding the typical lesions of the disease in the intestines, the liver and the kidneys.—*Le Bulletin Médical*, No. 45, 1889.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the *Treasurer*, Richard J. Druggison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, AUGUST 31, 1889.

## PROGRESSIVE NEUROTIC MUSCULAR ATROPHY.

J. HOFFMAN bestows the above name on an affection of which he reports an original case, with further observations on three cases which had been previously described by F. Schultze, and an abstract of the literature of the subject. The disease seems to be a rare one, but he finds observations by Eulenburg, Eichhorst, Hammond, Charcot and Marie, Herringham, Tooth and Osler. It is in a marked degree hereditary, usually affecting several members of a family, and descending, in some of the recorded cases, to the sixth generation. Males are more frequently affected than females, and healthy females, in families subject to the disease, may bequeath it to their male offspring.

It may appear in infancy, and usually develops in early life, but cases are recorded in which the first symptoms were observed after thirty years of age. It probably begins with atrophy of the small muscles of the feet, but is apt to escape attention until the muscles of the legs become involved. Next in order, the small muscles of the hands are attacked, and subsequently the forearms, the thighs, and, in some cases the muscles of the trunk are invaded. Deformities result, varying according to the degree in which the different muscles are affected. The feet assume the position of talipes equinus, varus or equinovarus, the hands that of "main en griffe." These deformities, with the striking differences which usually exists between the degree of atrophy of the distal and the proximal segments of the limbs, impart a very characteristic appearance to

the patients. The affection is symmetrical, and proceeds from the most remote segments of the limbs toward the trunk. Although there is a tendency to ankylosis of the joints there are no contractures. Fibrillar twitchings of muscles has been observed in some cases. Tendon reflexes and mechanical excitability gradually disappear. The same is true of the electrical reactions: at a certain stage of atrophy the "reaction of degeneration" is present: ultimately all response to both faradic and galvanic currents ceases. Sensibility is impaired in less degree than the motor functions, and there is no uniform relation between the two.

Two autopsies are on record, one by Virchow and one by Friedreich. In both the muscles and nerves of the parts involved were found to present the changes characteristic of the degenerative atrophy of the nerves. Sclerosis of the columns of Goll was found in the spinal cord. From the course of the disease and the post-mortem appearances the author concludes that it is primarily an affection of the peripheral nerves. The prognosis, as to recovery, he considers entirely unfavorable, although the disease may be arrested for an indefinite period, and is not incompatible with long life. No cases are on record in which it proved directly fatal, but the possibility of such a result cannot be excluded. No remedies, thus far, have seemed to be of any avail.<sup>1</sup>

## THE ERRORS OF STATISTICS.

It is unfortunate that in an era when many conclusions are necessarily dependent upon statistical computations, a neglect of technical mathematical training often vitiates both a writer's deductions and his reader's apprehension of them. So common is this sort of ignorance, even in otherwise educated circles, that, outside of a comparatively small coterie of cautious, and especially cultivated algebraists, the civilized population is about equally divided between those who sneeringly remark that "figures can be made to prove anything," and those who overconfidently derive preposterous fallacies from insufficient data. In no pursuit is unintentionally false logic more mischievous in its results than in that of medicine, and we therefore offer no apology for presenting certain facts which, if

<sup>1</sup> Archiv. für Psychiatric, xx, 3

they be tediously familiar to a choice few of our readers, may be useful to the majority.

Despite the popular proverb, figures will not lie if they be properly interrogated; but the accuracy of their response will be proportional to their multitude, and the interpretation of their oracles must be guided by a knowledge of the law of such proportion. Argument is hardly needed to show the unreliability of percentages drawn from a very small number of data: No sane person, having seen but four cases of a rare disease, two of which were fatal, would assume that the average mortality of the malady would always be 50 per cent., but many people fail to consider that a similar, though constantly diminishing, margin of uncertainty pertains to increasingly numerous groups of figures.

To determine this "possible limit of error," several formulæ—all leading to the same result—are given in treatises on statistics; the simplest being that of Poisson, namely: If  $q$  represent the total number of observed cases, and  $p$  the number of the particular class of which it is desired to calculate the proportion as a clue to the probable general average, the "limit of error"

will be  $2\sqrt{\frac{pq(q-p)}{q^3}}$  or, what is the same thing,

$\sqrt{\frac{p(q-p)}{q}}$  Applying this rule, and adhering

for the present to rates of mortality, it will be found that if our record comprise 100 persons, with 10 deaths, the error-margin is 8:48, so that, instead of 10 per cent., successive groups of 100 may yield as much as 18.48, or as little as 1.5 per cent.; if our total be 200, with 20 deaths, the possible error is 6, and the general average may vary between 16 and 4 per cent.; with 500 persons and 50 deaths, the allowance is 3.8, and the possible variation of subsequent percentages from 13.8 to 6.2; if we have as many as 1,000, with 10 per cent. of deaths, a second thousand may give a rate of 12.7 or 7.3; and it is not until we reach a total of 10,000 that the limit of error is reduced to less than 1. Of course, the extent of the possible error will vary with the value  $p$  in the equation, even when  $q$  remains constant. Nescience in this respect renders worse than worthless—because misleading—many painstaking contributions to medical literature, and invalidates, a large part of the work industriously done in the domain of vital statistics. If a sur-

geon perform a novel operation on forty patients, of whom thirty-two recover, he is apt to announce—and to believe—that his procedure reduces the mortality of such-or-such a grave disease to 20 per cent., unconscious that his own figures intimate that of his next series of forty, fifteen may die, or all survive. Estimates of the movement of population in minor communities; "experience tables" of life assurance companies; in short, all prognostications of averages based on finite numbers, require correction according to the rule above defined, and only he who knows just how many "grains of salt" to season them wherewith can profitably digest them.

#### THE GERMICIDAL ACTION OF BLOOD.

The explorations in science are carried on with the greatest vigor in different directions at different times. It is now over three years since Metschnikoff promulgated his phagocyte theory. During this time it has met with the greatest opposition. NUTTAL and BUCHNER<sup>1</sup> have added materially to our knowledge of the germicidal action of blood. Both defibrinated and freshly-drawn blood manifest a decidedly deadly action upon bacteria for more than four hours after it has been drawn from the body. This is most marked toward the pathogenic bacteria. For example, the number of anthrax bacilli in a given quantity of material was reduced in two hours from 4,800 to 56 by being mixed in a test-tube with defibrinated blood; and three hours later only three living bacilli remained. Almost as remarkable a germicidal influence was manifested toward other pathogenic bacteria. The destruction of putrefactive bacteria is, however, much less marked, and against some of them, at least, the blood manifested little germicidal influence. This is in accord with the latest ideas of the origin of parasitism.

These investigations open up a new field of inquiry and thought which promises a reorganization of our ideas of infection. We are brought back to consider the animal body a colony of individual cells, the integrity of which when attacked by parasitic bacteria depends upon the issue of the struggle for existence between individuals of the invading parasites and the individual cells of the body.

<sup>1</sup> Ueber die bakterientödtende Wirkung des zellenfreien Blutserums. Centralblatt für Bakteriologie und Parasitenkunde. V. Band, No. 25, page 817, et seq.

## EDITORIAL NOTES.

## HOME.

**FACULTY CHANGES.**—The Toledo Medical College have elected Dr. J. T. Woods, formerly Professor of Physiology in the Cleveland Medical College, to the chair of Orthopædic Surgery; Dr. F. B. Robinson, of Grand Rapids, Wis., to the chair of Anatomy; and Dr. H. G. Blaine, Editor of *The Medical Compend*, lecturer on Diseases of the Nervous System.

**CANADIAN MEDICAL ASSOCIATION.**—The annual meeting of this Association recently held at Banff, was a very successful one. The work was good and the papers creditable. Dr. James Ross, of Toronto, was elected President, and the next meeting will be held in the latter city.

**COLUMBUS MEDICAL COLLEGE.**—The Secretary of this College, Dr. J. M. Dunham, writes us that they require and make examinations of students, before entrance, in literary attainments. It was not so stated in the table in our Special Edition of May 25.

**TRANSACTIONS OF THE AMERICAN MEDICAL ASSOCIATION.**—Any member of the Association desirous of procuring volumes of the Transactions from 1844-82 at a reduced price, can do so by addressing the Business Department of THE JOURNAL.

**THE AMERICAN DENTAL ASSOCIATION.**—This Association concluded its sessions at Saratoga on the 9th inst. after electing the following officers: President, Dr. M. W. Foster, of Baltimore, Md.; first Vice-President, Dr. A. W. Harlan, of Chicago; second Vice-President, Dr. J. D. Patterson, of Kansas City, Mo.; Recording Secretary, Dr. George H. Cushing; Corresponding Secretary, Dr. Fred Levy, of Newark, N. J.; Treasurer, Dr. A. H. Fuller, of St. Louis, Mo. The Association will meet at Excelsior Springs, near Kansas City, next year.

**A NOTE OF WARNING.**—Dr. R. Harvey Reed, Health Officer at Mansfield, O., has communicated the following to the *Mansfield Daily News*: "In view of the fact that the use of the so-called 'Elixir of Life' (which consists in injecting under the skin the raw liquid obtained from crushing and expressing the juice of the fresh testicles of the lamb or other animal) has developed a marked case of erysipelas in our city, which disease was

clearly traceable to the use of this liquid, and developed from the punctures where said liquid was injected, until almost the whole of both forearms were involved, which was accompanied by a chill, vomiting, fever and a rapid pulse, with marked redness and swelling of both forearms; and in view of the fact that numerous other cases of erysipelas and blood-poisoning have been reported occurring from the use of this liquid, saying nothing of several deaths occurring from its use, which clearly demonstrate that its use is attended with danger to the public health, it therefore becomes our duty to warn the public of the danger attending its use. . . . ."

We learn that, since the issue of the above, the man has an abscess at each of the punctures, three on the right and two on the left arm, and one on the right leg. Dr. Reed lanced them and they yielded from  $\frac{1}{2}$  to 1 oz. each of unhealthy pus, and after all giving no relief whatever for his chronic troubles.

**AMERICAN PEDIATRIC SOCIETY.**—The meetings of this Society are announced to take place at the Army Museum Building, Washington, D. C., September 20 and 21. One of the afternoon meetings will be held in the Johns Hopkins Hospital, Baltimore, Md., by invitation of the Director of that Hospital. A large number of papers have been promised. Dr. A. Jacobi is the President, and Dr. Thos. L. Latimer, Chairman of Committee of Arrangements.

**PREVENTION OF TYPHOID FEVER.**—The State Board of Health of Kentucky has issued a circular to the health officials and people of the State impressing upon them the necessity of preventive measures to stop the gradually increasing prevalence of, and mortality from, typhoid fever. The circular goes on to say:

Two methods of prevention, having the same general object in view, are to be recommended. The first involves the thorough disinfection of all discharges from the bowels of typhoid fever patients. This is best done by the use of a solution of chloride of lime, 8 ozs. to the gallon of water, using a quart of this solution for each discharge, and allowing it to stand in the vessel at least one hour before emptying. A solution of corrosive sublimate, 2 drachms to the gallon of water, will answer the same purpose, but requires to remain longer in contact with the material to be

disinfected. Bed and body linen soiled by such patients should be disinfected by the use of the same solution or by boiling.

The second method relates to avoiding the use of suspicious water, and especially well water, and where this cannot be done, to boil such water before it is used for drinking purposes. In the absence of a pure and well guarded public water supply, properly stored cistern water is probably open to least objection.

The effectual practice of these methods will require intelligent care and some expense, but it is confidently believed that their general adoption would result in the practical disappearance of a disease which is not only a disgrace to our civilization, but an annual scourge and tax upon the people of Kentucky, in comparison with which yellow fever and cholera sink into insignificance.

**THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.**—The annual meeting of this Association will be held in Evansville, Ind., on the 10th, 11th and 12th of September. The officers for this year are: President, Dr. Geo. J. Cook, Indianapolis; Vice-Presidents, Dr. J. A. Larrabee, Louisville, and Dr. J. D. Griffiths, Kansas City; Secretary, Dr. R. L. Thompson, St. Louis; Treasurer, C. W. Chapman, Toledo, O.; Committee of Arrangements, Dr. Edwin Walker, Dr. Lud Worsham, Dr. Charles Knap, with Dr. A. M. Owen, Chairman; Dr. C. P. Bacon, Chairman Committee of Arrangements, and Dr. Geo. P. Hodson, Chairman of the Committee on Exhibits.

Traffic Manager J. G. Grammer, who is Chairman of the Committee on Transportation, has succeeded in securing a one and one-third rate on all the roads in the Ohio and Mississippi valleys, which insures a large attendance.

This organization is the outgrowth of what was formerly the Tri-State Medical Association, which at first only included Indiana, Illinois and Kentucky, but its usefulness to the profession has become so great that it was found necessary to enlarge its territory, and as it is now constituted, is second only in importance and numbers to the American Medical Association, to which it is auxiliary and subordinate.

This Association is rapidly attaining the object of its formation—a thorough organization of the members of the regular profession of the entire Mississippi Valley, thus to foster, advance and

disseminate medical knowledge, to uphold the honor, and to maintain the dignity of the medical profession.

Last year members in the Gulf States were unable to attend on account of the yellow fever quarantine. This year nothing will hinder a full attendance from all sections of the country, as questions of importance to the entire profession of the South and West will be before the Association for consideration.

The importance of this Association in bringing together the members of the profession within this territory must be apparent to everyone, as there are many interests in common and individual welfare that can best be promoted by the advancement of the interests of all.

The preliminary programme contains a list of ninety-seven papers. It is expected about 800 members will be in attendance.

**THE ADDRESS OF CLAUDIUS G. WHEELHOUSE, F.R.C.S., PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.**—By special courtesy we were able to present to our readers in *THE JOURNAL* of August 24 the address of the President of the British Medical Association, which was delivered at its annual meeting, August 13, 1889. We are confident that it has been read with special interest. We only regret that the limited space at command did not permit us to publish it entire. His able review of the progress of medicine during the last century is alike interesting to its readers in Europe and America.

**OMISSION.**—In the report of the Section of Ophthalmology, it omitted to state that the paper submitted by Dr. F. C. Hotz, of Chicago, was read by title and referred for publication. It will appear in its order in *THE JOURNAL*.

**THE AMERICAN PUBLIC HEALTH ASSOCIATION** will hold its seventeenth Annual Meeting at Brooklyn, N. Y., on Oct. 22, 23, 24 and 25, 1889.

**DR. J. SOLIS-COHEN**, of Philadelphia, was recently elected Honorary Fellow of the British Laryngological and Rhinological Association.

*THE Sanitary News* draws attention to the fact that silk thread is soaked in acetate of lead to increase its weight, and persons who pass it through the mouth in threading needles, and then biting it off with the teeth, have suffered from lead poisoning.

## TOPICS OF THE WEEK.

## MEDICAL JURISPRUDENCE. CASES RECENTLY ADJUDGED.

*Drunkenness.*—Voluntary drunkenness which precludes a comprehension of the nature of the act, or recognition of the person killed, is no excuse for murder; but *mania a potu*, or any insanity or permanent unsoundness of mind resulting from the use of intoxicating liquors, will exempt one who commits a murder from punishment therefor. *Beck v. State*, 76, Ga. 452.

*Employment.*—A physician employed by the conductor of a train to care for a man injured by the train can recover against the railroad company for his services if, after knowledge or his employment by the conductor, the company failed to notify him that it would not be responsible. *Terre Haute & I. R. Co. v. Stockwell* (Ind.) 20 N. East. 650.

*Expert.*—When a medical expert is asked to give his professional opinion to a jury, not upon matters within his own knowledge, but upon an hypothetical case founded upon the testimony of witnesses previously examined in the case, the questions to him must be so shaped as to give him no occasion to mentally draw his conclusion from the whole evidence, or a part thereof, and from these conclusions, so drawn, express his opinion, or to decide as to the weight of evidence or the credibility of witnesses; and his answers must be such as not to involve any such conclusion so drawn, or any opinion of the expert as to the weight of the evidence or the credibility of witnesses. *Kerr v. Lunsford* (W. Va.) 2 L. R. A. 668, 8 S. E. 493.

The opinion of medical experts, founded on testimony already in the case, can only be given on an hypothetical case; and the hypothesis must be clearly stated, so that the jury may know with certainty upon precisely what state of assumed facts the expert bases his opinion. *Id.*

In putting hypothetical questions to expert witnesses, counsel may assume the facts in accordance with their theory of them. It is not essential that he state the facts as they exist, but the hypothesis should be based on a state of facts which the evidence in the cause tends to prove. *Id.*

The opinion of an expert witness as to the nature and extent of an injury to a person is not inadmissible because based in part on the statements of the injured person. *Louisville, N. A. & C. R. Co. v. Snider* (Ind.) 20, N. East. 284.

*Insanity.*—Insanity is a fact that cannot be proven by reputation, or by a witness who is not an expert, unless he first gives the facts upon which his opinion is based. *Grubb v. State* (Ind.) 20 N. East. 257.

Where there is an issue made as to sanity, and evidence is introduced under it tending to show insanity, there is no presumption to be indulged one way or the other. *Missonri Pac. R. Co. v. Brazil* (Tex.) 10 S. W. 403.

A defendant in a criminal case who raises the defense of insanity must prove it by a preponderance of evidence; and this applies as well to the causal connection between the fact of insanity and the crime committed as to the insanity itself. *Gunter v. State*, 83 Ala. 96.

A person, though of weak mind, but with sufficient capacity to distinguish right from wrong in respect to the particular acts charged, is accountable for his acts, and the plea of insanity will be unavailing as a defence for crime. *Anderson v. State* (Neb.) 41 N. W. 357.

An instruction as follows: "If you believe from the evidence that defendant fired the shot that caused the death of the deceased, and that, at the time of the controversy, defendant was in such a mental condition as to distinguish the difference between right and wrong, then he was responsible for his act, and you must convict," is erroneous, as it does not, standing alone, state a correct legal proposition. *Kearney v. People*, 11 Colo. 258.

Moral insanity, as distinguished from mental derangements, is not an excuse for crime, and does not exempt from punishment therefor. *People v. Kerrigan*, 73 Cal. 222.

*Malpractice.*—In an action against a physician, based on his lack of care or skill, the burden of proof to show such lack is on the plaintiff. *State Jenney v. Housekeeper* (Md.) 2 L. R. A. 587, 19 Md. L. J. 917, 16 Atl. 352.

The party who allows a surgical operation to be performed is presumed to have employed the surgeon for that purpose, and the burden of proof to show lack of consent is on the party alleging it. *Id.*

If physicians attending a woman deem it necessary, for the preservation and prolongation of her life, to perform an operation, they are justified in doing so if she consents, whether her husband consents or not. *Id.*

The degree of care and skill required of physicians is that reasonable degree of care and skill which physicians ordinarily exercise in the treatment of their patients. *Id.* --EWELL in *North American Practitioner*

## SPLENECTOMY.

A successful case of splenectomy for enlargement and displacement of the organ is reported by Sir Spencer Wells. The patient was a young married woman, aged 21, who had suffered from ague when a child. Soon after her marriage, an abdominal tumor which she had had for several years began to enlarge, and was thought to be connected with the left ovary. It continued to increase in size till it lay in front of the uterus, extending from the pubes to the umbilicus, and measuring 9 inches transversely. Sir Spencer Wells diagnosed it to be an enlarged displaced spleen. After an attack of peritonitis, which was judged to be due to hæmorrhage into the spleen substance, the tumor was aspirated, 10 pints of thick reddish-brown fluid being drawn off. Microscopically this was found to contain mainly broken-down red blood corpuscles and numerous leucocytes. As the fluid quickly reaccumulated, and the patient's condition became critical, Sir Spencer removed the tumor on May 13, 1888. During the operation the cyst wall ruptured, and a large quantity of fluid, similar to that withdrawn by aspiration, rushed out. The solid part of the tumor, consisting of hypertrophied spleen tissue, weighed 4 lbs. There were extensive adhesions to intestines, uterus, etc. One part in front was so firmly adherent that it was decided to leave a portion of the cyst wall, measuring 3 to 4 inches from above downwards, 2 to 3 from side to side, and 4 inch

in thickness. Sir Spencer Wells decided not to drain, and after securing the splenic vessels with silk ligatures stitched up the wound with fine silk, including sac wall, peritoneum and integument. The operation, which lasted fifty minutes, was performed under carbolic spray, and the wound was dressed antiseptically; scarcely any blood was lost from the splenic pulp, but the patient was much exhausted after the operation. The wound had to be partly reopened a week later to give exit to pent-up discharge. The pus-forming cavity did not communicate with the peritoneum. Strict antiseptic precautions were employed and the sac gradually contracted into a sinus. On July 22 she was perfectly well and only a small superficial sore remained. A year after the operation she continued well, and could exert herself in any way as well as ever. The abdominal cicatrix was firm and nothing abnormal could be discovered either in the abdomen or the pelvis. A report by Dr. Dreschfeld on the blood, dated June 21, 1889, more than a year after the operation, states that on microscopical examination it appeared perfectly normal. The red corpuscles were of normal size and appearance; the leucocytes were of normal size and were present in normal proportion. The quantity of hemoglobin was between 75 and 80 per cent.—*London Medical Recorder*.

#### ON SUPRA-VAGINAL AMPUTATION OF THE UTERUS.

Dr. Petr. A. Rakuza, of Odessa, Russia, has made the operation in twelve cases. In nine it was resorted to on account of uterine fibro-myomata; in a tenth case on account of hæmatometra with hæmoatsalpiux and hæmatocolpus; in an eleventh the amputation became necessary in the course of an unusually difficult double ovariectomy, where there were met with extensive and extremely dense adhesions of cysts with the broad ligaments and womb; in the remaining case, Porro's Casarean section for osteo-sarcoma of the pelvis and femur was performed. In seven cases the operation was made after an extra-peritoneal method (first described by Kleberg in 1875), all the patients making good recovery. In the other five cases, an intra-peritoneal operation was performed, with three recoveries and two deaths from peritonitis. Dr. Rakuza's general deductions are these: 1. The extra-peritoneal method gives by far better results than the intra-peritoneal. 2. Even under strictest antiseptic precautions the intra-peritoneal amputation is always associated with the danger of a secondary infection (through the cervical canal). 3. The operation is justified only in cases of pedunculated fibroids and in such ones where the stump is very short.—*Transactions of the Third General Meeting of Russian Medical Men at St. Petersburg, 1889, No. 10.*

#### CHINESE DOCTORS

Tcheng-Ki-Tong, a high military mandarin, has been edifying the world with some remarkable illustrations of the esteem in which native physicians are held in China. One of them having advertised that he had an infallible remedy for curvature of the spine, a hunchback applied to him and asked if he could straighten his back. The doctor undertook to do so, and placed the unfortunate patient on his back on a flat board. He then placed a

similar board on his chest and abdomen, and loaded it with heavy weights and stones. The result of this novel orthopædic surgery was that the patient was straightened out so effectually that he died on the spot. The quack claimed his fees on the ground that he had kept his promise; the bargain was that he should straighten his patient's back, but nothing had been said about his life! In China, it appears, the distinction between physicians and surgeons is more sharply defined than with us, and every man is expected to stick to his own branch of the profession. A rich merchant was struck by an arrow, which remained in the wound. The principal surgeon of the place was sent for, and after insisting on pocketing his fee in advance cut off the projecting end of the arrow, leaving the point buried in the patient's body. On being asked to extract it, he said medical etiquette would not allow him to trespass on a brother practitioner's province; the arrow being inside the body, the case was clearly one for a physician! An old Chinaman gave the following practical advice as to how to find the most eminent doctor in a strange place: "Count the number of ghosts crouching about the doctor's doorsteps; the one most in vogue has always the largest number."—*London Medical Recorder*.

#### TO PUNISH DRUNKARDS.

The Legislature of Minnesota at its last session, apparently realizing the failure of its high license enactment of a few years ago, ostensibly for the prevention of drunkenness, but in reality authorizing the means by which it may be privileged, passed a law to punish drunkards. The new law provides a fine of not less than \$10, nor more than \$30, or by imprisonment for not less than ten, nor more than forty days. For the second offense, by imprisonment for not less than thirty, nor more than sixty days, or by a fine of not less than \$20, nor more than \$50. For the third or all subsequent offenses, by imprisonment for not less than sixty days nor more than ninety days.

It is to be hoped that this law will be vigorously enforced. *The Sanitarian* has constantly maintained that the true criminal is he who gets drunk; and that it is no more reasonable to hold the liquor seller guilty of promoting drunkenness than it would be to hold the grocer guilty of promoting theft because his goods are sometimes stolen. Make drunkards odious and cease pampering them as unfortunates and encouraging them to hold other persons responsible for their sins, and drunkenness will speedily go out of fashion.—*The Sanitarian*.

#### A SECOND EDITION OF THE SIAMESE TWINS.

*The Weekly Medical Review* says: "From Wabash, Ind., is reported the birth of female twins inseparably connected at the hips and lower part of the abdomen. There is a head for each of the two bodies, and enough legs to go around; these protrude from each side of the body where the trunks are connected at the hips. The spinal column is continuous throughout, but no other vital organs are connected. Each child breathes, pulsates, and is nourished independently of the other. Both have free use of their respective limbs. Their joint weight is 12 lbs., and they are plump and hearty."

## SOCIETY PROCEEDINGS.

## Medical Society of the District of Columbia.

*Stated Meeting, February 13, 1889.*THOMAS E. MCARDLE, VICE-PRESIDENT, M.D.,  
IN THE CHAIR.

## REPORT OF MICROSCOPICAL COMMITTEE.

The Committee on Microscopy reported that the supposed gall stones presented by Dr. Hoehling were examined chemically and microscopically, and found with one exception to be true gall stones.

The growths of the uterus presented by Dr. J. T. Johnson, January 16, were myofibroma. The ovary presented at the same meeting was in a state of cystic degeneration. The portion of uterus presented by him February 6, can be described as a fibromyoma. The part projecting into the cavity of the uterus was in a state of inflammation and ulceration.

DR. GEORGE N. ACKER presented the following case and specimen :

## HYDRONEPHROSIS IN A CHILD.

Willie Smith, æt. 5, colored ; father and mother living. Child has never been well since birth, has always been small for age, and emaciated. About one month ago was taken with a bad cold, and cough. The cough has continued up to the time of admission, and the child has gradually become more emaciated.

Present condition January 23 : General appearance, very much emaciated, looks as if he might be 3 years old instead of 5. Has a marked phimosis. Temperature 97.4°. Has a dry hacking cough, no expectoration. Diminished resonance over both lungs anteriorly, more particularly on left. Large and small moist râles over both lungs anteriorly and posteriorly. Tongue coated white, great thirst, ravenous appetite, seems to be somewhat constipated. Abdomen pendulous and tympanitic.

24th. Temperature at 11 A.M., 103°. Feet swollen and œdematous.

25th. Vomited undigested milk, temperature ranges from 99° to 102.5°.

26th. Œdema of feet and legs diminished, abdomen less distended.

27th. Temperature ranges from 100.5° to 102.5°.

29th. Abdomen much more distended, has vomited milk three times in last twelve hours. Temp. at 9 A.M. 104.2°.

30th. At 10 30 A.M., temperature 106.

31st. Has vomited twice in last twenty-four hours. Has been passing for past three or four days, an unusually large quantity of urine. Chemical and microscopical tests show it to be normal. Also has slight diarrhœa.

February, 1st. Temperature ranges from 101° to 102.2° ; three passages from bowels to-day.

2d. Temperature ranges from 100° to 101°.

3d. Very weak, temperature ranges from 99.5° to 102.8°, pulse too weak to be counted.

4th. Died at 3 A.M. from exhaustion.

Necropsy held eight hours after death. Rigor mortis, slight. General appearance very much emaciated, abdomen enormously distended. On opening the chest a considerable quantity of sero-purulent fluid escaped from the pleural cavity, left side. The left lung was thickly studded throughout with tuberculous masses, the upper lobe being entirely consolidated. A few tubercles were found in the right lung ; the right lung was also in a state of chronic hyperæmia. An abnormal quantity of fluid was found in the pericardium. The liver was uniformly enlarged, small caseous masses were discovered at the junction of pancreatic duct with the duodenum. Both ureters were dilated, and contained a considerable quantity of urine. Numerous tubercular masses were found over external surface of spleen.

Up to within four days of patient's death, he seemed to be very bright, and free from pain. During his entire stay in hospital he passed a large amount of urine. During the last four days of his illness he seemed to be in great pain.

DR. BERMAN did not think that this was a case of hydronephrosis as there were no symptoms recognized during life indicating disease of the kidneys, and the microscopic appearances would not indicate degeneration of these organs. The child died of tuberculosis, the post-mortem revealed a dilatation of the ureters and hydronephrosis is diagnosed. Is the name justified by the dilated condition of the ureters? He did not think so, although Dr. Acker accepted the diagnosis on the authority of Dr. Lamb.

DR. THOMPSON : Was there any cause in the bladder or urethra to account for the dilatation of the ureters.

DR. LAMB had presented about a year ago a specimen of dilatation of the ureter in a newborn child. Dr. Acker's case was undoubtedly congenital hydronephrosis. The opening in the bladder was normal, and the bladder itself was thick but not diseased. The trouble was above the bladder. There was a constriction of either ureter just below the kidney, but no obstruction. The pelvis of the kidney was dilated and the pyramids flattened. This is what the books call hydronephrosis. This was the second case he had seen.

DR. THOMPSON : Would there not be a cause for a congenital condition of this kind?

DR. LAMB : As a rule, no obstruction is found. None was found in either of the two cases he had seen.

DR. THOMPSON : Congenital deformity expresses a fact but not a pathological fact. There

must be a cause for such conditions. He gave the case of a man, æt. 50, whose ureter was distended to the size of the large intestine. He had examined the opening into the bladder, but the probe passed through it. He concluded that there must have been a valvular opening of the ureter into the bladder causing backward pressure. After death a probe may pass through many such openings, although there may have been an obstruction during life.

DR. A. F. A. KING: How are we to know that there was not a congenital stricture of the urethra since that canal was not examined? The bladder has ruptured from congenital stricture of the urethra. If there had been a stricture of the urethra the dilatation of the ureters could be easily accounted for by the backward pressure of the urine.

DR. BERMANN objected to the term used, but would ask Dr. Lamb, assuming that there was no hydronephrosis, what he would call a case with such a dilatation of the ureters?

DR. LAMB: This is what the books call hydronephrosis.

DR. BERMANN would call it dilatation of the ureters.

DR. KING: The post-mortem appearances show no evidences of obstruction of the ureter below the dilatation. There may have been some pressure exerted during fetal life causing obstruction and dilatation; after birth, the pressure being removed, the obstruction would disappear and the ureters remain dilated.

DR. LOVEJOY: If we accepted Dr. King's belief that the obstruction existed at the neck of the bladder or in the upper part of the urethra, how could we account for the dilatation of the ureters as far as one inch from the kidneys at the seat of the constriction? The dilatation should be above the obstruction and not below it.

DR. KING: One part of the ureter may be more dilatatable than another.

DR. ACKER accepted the diagnosis of hydronephrosis because the kidneys were softened and the ureters were distended to the size of the colon.

DR. D. S. LAMB presented two cases of

#### INTRA-CRANIAL HÆMORRHAGE, WITH SPECIMENS.

This specimen consists of the lower half of the brain, showing a dark blood clot under the arachnoid membrane covering the pons varolii and medulla oblongata, and extending forwards over crura cerebri, intercavernous parts and posterior portion of orbital lobes.

The patient was a white woman, single, æt. 19, who was said to have been struck on the back of the head with the blunt end of an axe. Some time afterwards she was admitted to hospital with double phlyctenular keratitis and conjunctivitis; marked headache, photophobia; the headache

was frontal, intense at times, but thought to be due to the disease of the eyes. She had also hip-joint disease, not however, requiring treatment. She recovered from the disease of the eyes and was discharged. Had had no symptom suggesting disease of brain. She then went into the Women's Christian Association Home, and made no particular complaint till December 3. When after a few hours' nausea, faintness and staggering movements, she died. Attended by Dr. Mary Parsons.

The post-mortem examination by Dr. Lamb showed the condition described in the specimens; also the following: Face pale; no scar on scalp; no injury to bone; adhesion of dura mater to skull only ordinary; but there were several long bands of adhesion of pia mater to tentorium cerebelli on right side; and the pia mater was congested. The blood described extended into the 4th ventricle and down the spinal canal as far as could be seen from the cavity of the skull. There was bloody serum in the lateral ventricles. Both lungs contained bloody serum. The heart was somewhat enlarged; the aortic and mitral valves slightly thickened. Ascending aorta showed a large atheromatous patch. Liver congested, spleen, stomach and intestines normal, kidneys normal and bladder full. The inner surface of the mouth of the uterus showed a fringed-like growth, and the cavity contained muco-pus. Ovaries enlarged; in the right was a large cavity containing blood; its inner surface ridged; the wall very thin and ruptured in handling. The left ovary was thickened; cortex contained many large cysts filled with white granular matter.

The next specimen consists of the lower half of the brain showing large clots in the right cerebral hemisphere; the hæmorrhage has caused extensive laceration, involving the frontal, parietal and occipital lobes, corpus striatum and thalamus opticus; but opening into the lateral ventricle only through the anterior part of the corpus striatum; the blood thence finding its way into the left ventricle through the foramen of Monro.

The patient was a colored man, æt. 52; had been a widower, but was married just a week before he had a stroke of paralysis. He was a large muscular man with thick neck; medium height and about 180 lbs. weight. He had eaten heartily on the evening of December 5. The next morning he was found in a stupor, from which he was aroused with difficulty; respiration stertorous; there were spasmodic movements of the right arm; right side of face paralyzed; left side of body also; pupils dilated and insensible to light; dysphagia; unable to protrude his tongue; tenderness on right side of neck aggravated by movement of head; urination involuntary; constipation; speech thick. Pulse at first full and quick; afterwards weak and frequent.

He died eight days after seizure. His mother had died of apoplexy; a sister from softening of brain. He was an inveterate smoker; used stimulants in moderation. Attended by Dr. S. R. Watts.

These typical specimens are presented for contrast. The hæmorrhage into the substance of the brain in the one case, that of the old man; and into the membranes in the other, that of the young woman. In both cases the accident was caused doubtless by rupture of a diseased blood-vessel. But the cause of the disease of the blood-vessel was probably different in the two cases.

In that of cerebral hæmorrhage, there is a history which seems to show a hereditary tendency to disease of blood-vessels; the mother died of apoplexy, a daughter, of softening of brain. Probably also we should give some credit to the man's plethoric habit as a predisposing cause, although such a cause is disputed. How far an inveterate habit of smoking may produce disease of blood-vessels of the brain is an interesting question. The absence of symptoms suggesting disease of thoracic or abdominal viscera was the reason for not including these in the examination; it is possible that there was some disease of heart or blood-vessels of those cavities. It seems altogether likely that the rupture of the diseased vessel in the brain was induced by the sudden fulness and pressure following a hearty meal, especially as the man went to sleep soon afterwards. It is worthy of note that the hæmorrhage took place into the brain substance just outside the corpus striatum, the usual situation. To the naked eye the large vessels appear normal; the degeneration, probably fatty, I presume involves only the minute vessels.

In the case of the young woman, there is to the naked eye also no appearance of disease of blood-vessels; but we can hardly doubt that there is disease. There is no history of hereditary tendency, either positive or negative. But there was marked atheroma of the ascending aorta; and the heart was somewhat enlarged and its valves thickened; there was also old hip-joint disease. It is easy to believe, therefore, that there was some disease of the blood-vessels of the brain and membranes, possibly cerebral aneurism, which is said to occur oftener in children between 10 and 20 years of age than at any other period of life. I am unable to trace any connection between the reputed injury received and this hæmorrhage, although quite ready to believe that there may have been some connection.

I did not mutilate the specimens to ascertain the particular vessel involved in each case, because it is so seldom that the vessel can be found even with the greatest painstaking.

DR. THOMPSON was surprised that one of these cases did not have paralysis, and could only account for the absence of such symptoms by the

fact that the patient did not live long enough for them to be recognized.

DR. MARY PARSONS: The patient screamed and staggered to the bath room, and then lost the use of her limbs. She was conscious and talked rationally up to five minutes of her death.

DR. A. A. HOEHLING, U. S. N., presented a specimen of

#### TAPE-WORM.

The patient, a marine, aged 24 years, native of Chicago, Ill., enlisted last November; so that he probably had the worm before he entered the service. First passed segments of the worm about January 21, 1889, and has never felt a bad symptom from its presence. On February 6, after breakfast, he was told to eat nothing more until his treatment should have taken place. That night he was given 10 grains of blue mass. At 11 o'clock on February 7 he took 15 grains of the oleo-resin of male fern every 15 minutes until he had taken eight doses; in all 5 ij. In an hour after the last dose of male fern he was given one ounce of castor oil. That afternoon he had four stools, and passed this worm in divided sections. A good deal of the smallest section, near the neck, has been found; but the slender inch of real neck and the pin-head sized head have not been discovered. Flint tells us that the head is rarely found after treatment for tape-worm, but that if the worm breaks off very near the head there is not enough body left to nourish the remainder, and a cure is accomplished. Striimpel says that in attempts to pull the worm away from the bowel where the head fastens itself to the mucous membrane, there is usually a separation caused near the neck and the head remains clinging to the spot of its attachment. I have treated about six men for this complaint, and have not seen the head of the worm yet. This specimen I believe to be of the variety known as the *tenia solium*. As I have usually been the shipmate of my patients for two or three years, I have had the opportunity to observe that tape-worm has a decided tendency to reappear, even after two or three lots of segments have been gotten rid of by treatment in the course of a cruise.

DR. A. A. HOEHLING, U. S. N., read a paper on THE OLIVE OIL TREATMENT OF HEPATIC COLIC.

Prof. H. W. Wiley, of this city, tells us in *The Medical News*, of July 28, 1888, that "Dastre, in a recent study of the action of the bile in fat digestion (*Comptes Rendus*, tome 106, p. 217) has shown that the pancreatic juice alone is not capable of digesting fats;" also that "these conclusions of Dastre have just been confirmed by the experiments of Prevost and Binet (*Comptes Rendus*, June 11, 1888, p. 1690). These investigators find that in dogs, when the bile is prevented from taking part in digestion, fat foods are voided unchanged."

In "Dalton's Treatise on Human Physiology," seventh edition, pages 181 and 182, it is stated that "the bile passes into the duodenum in much the largest quantity immediately after feeding. During the intervals of digestion it accumulates in the gall-bladder: and in animals which have been for some time without food the gall-bladder is usually distended with bile, while in those killed immediately or soon after feeding it is comparatively empty. At the commencement of digestion it is excited to contraction, causing a sudden flow of bile into the duodenum. After that time the discharge remains nearly constant."

Admitting all of the statements just quoted to be proven, we can formulate an explanation of the *modus operandi* of large doses of bland oils in removing gall-stones from the ducts in which they have been arrested. *Physiological action causes the removal of the obstruction.* What is more likely than that the ingestion of a large amount of one of the food oils should furnish a stimulus for the secretion of a proportion of bile relatively equal to the amount of oil to be digested? And would not this increased quantity of bile aid in the propulsion of the engaged gall-stone, firstly by lubricating it thoroughly, as well as by moistening completely the walls of the ducts which may be partially dry from occlusion of their lumen by the impacted gall-stone; and secondly, by the force of hydrostatic pressure from the proper direction for the expulsion of the calculus? Is it not probable that the contraction of the gall-bladder mentioned by Dalton, also adds to this hydrostatic pressure, both being called into play when the digestion of a large dose of oil begins?

We have then a force pushing the calculus from behind, the latter freshly moistened, and the ducts made more distensible by the new access of bile; and thus the stone reaches the duodenum. I might add that when, as is frequently the case, castor oil is given in these seizures there is no reason why the physiological actions just spoken of should not be called into play, and aid the therapeutical or purgative effects of the castor oil. We know that infants digest this oil very frequently, and therefore require a relatively large dose; and it is reasonable to suppose that adults also digest some of its bland portion.

We have empirical knowledge that attacks of hepatic colic have often been relieved by large doses of olive oil, and that in such cases solids have been voided that were regarded as true gall-stones. Dr. T. H. Streets, U. S. N., reports such a case in the *Medical Record* of April 14, 1888; in the *Medical News* of May 26, 1888, I reported a case in which prompt relief was afforded by olive oil, but no stone was found, nor was a close search made. On the other hand, Prof. D. W. Prentiss reports a case in the *Medical News* of May 12, 1888, in which relief was given

the patient, but the particles removed after large doses of cotton-seed oil were found to be soap, on examination by Dr. H. W. Wiley, as described in his article heretofore quoted.

Prof. R. T. Edes, in his text-book on "Materia Medica and Therapeutics," 1887, p. 287, speaks of the same sort of masses as "lumps of soap formed by the oil with the alkalies of the intestinal secretions." In conversation with Drs. Edes and Prentiss I learned that they do not deny that true gall-stones may be discharged during the treatment under consideration; but they take the position that semi-solid saponified masses of injected oil are sometimes passed, and that such substances have been mistaken for gall-stones.

DR. HOEHLING presented a case of

#### GALL-STONE COLIC TREATED BY THIS METHOD.

Henry T., marine, aged 46 years, native of Italy, was the patient who passed the gall-stones exhibited to the Society, and I am indebted to Dr. A. F. Magruder, U. S. N., for the notes of his case. He had his first attack of gall-stone colic Nov. 12. His bowels were opened by purgatives, and jaundice relieved in about two days, and he passed the two smaller gall-stones. No oil was given during this attack. On January 9 he had another acute attack of the same nature, lasting five hours, which was followed for several days by nausea and vomiting, with pain on pressure over the gall-bladder, abdominal tenderness and distension, and steadily increasing jaundice. Unable to procure a movement of his bowels until January 14, on which day he took about one quart of olive oil in divided doses, some of which he vomited up again, and in the afternoon his bowels were moved, attended by the passage of the two largest gall-stones that have been shown to the Society by me. His urine had become as dark as porter, and his skin looked a dark green. He had partaken of no food of any kind in four days, and had been troubled with singultus for twelve hours before his bowels were moved.

After the passage of the gall-stones he commenced to improve steadily, and he continues to do so. His wife states that during the olive-oil treatment he had a stool composed of "thick bile" after he had passed the calculi. She describes it as a gruel-like mass which would about fill a tea cup. We may well regard this grumous defecation as being a portion of the olive oil emulsified, or partially saponified, and discolored by biliary and fecal additions.

It is interesting to note that no semi-solid saponified lumps were found in this case, though a very large quantity of oil was taken. We might inquire how is the soap formed in those cases where it occurs. As many of these patients are early put upon an alkaline treatment I supposed that might account for the saponification: but experiments with a solution of bicarbonate of

soda added to olive oil in a vial, at the temperature of a warm room, did nothing to confirm this view. The alkalies found in the bowels never produce lumps of soap in a state of healthy digestion, so far as I am aware.

## FOREIGN CORRESPONDENCE.

### LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

*The International Congress on Dermatology and Syphilography—The International Congress on Hypnotism—The International Congress on Mental Medicine.*

Among the numerous International Congresses that are being held in Paris since the opening, in May last, of the Universal Exhibition, one of the most important is that on Dermatology and Syphilography. The meetings, which will extend from the 5th to the 9th of August, will be held at the Museum of the Hôpital St. Louis, than which, a more appropriate place could hardly have been selected for the purpose. The first meeting took place on the morning of the 5th inst., when more than 220 members, composed of French and foreigners, were present. Among the latter were the most distinguished dermatologists of their respective countries. This may be seen by citing the following names: Kaposi, Hans, Hebra, Neumann of Vienna, Malcolm, Morris, Hutchinson, Crocker of London, Duncan Bulkley of New York, Duhring of Philadelphia, Tarnowsky of St. Petersburg, Olavide of Madrid, Manassei of Rome, Zambaco of Constantinople. Besides Dr. Uuna, other distinguished dermatologists of Germany sent in their adhesion to the Congress but, at the last moment, they all withdrew, why and wherefore, remains a mystery. This of course has been severely commented on by the French, and not without reason, as it cannot be said that such a proceeding on the part of the German *savants* was in good taste. However, in spite of this unpleasant incident, it is anticipated that the Congress will be a great success. The first meeting was presided over by M. Ricord, the illustrious syphilographer and octogenarian, who, notwithstanding his advanced age, expressed himself willing to preside, and in very suitable terms welcomed the foreign members of the Congress. He was naturally the object of a veritable ovation. M. Peyron, the Director-General of Public Assistance, retraced the history and origin of the museum from Devergie, its founder, to the present time, which he said was the finest museum of its kind in the world, and where dermatology may be studied as on the living subject. This is due to the consummate skill of M. Baretta, the eminent modeller, who is the author of the incomparable collection

now to be seen in this museum. The bureau was next constituted, and Dr. Hardy, the well-known dermatologist, was elected the actual President of the Congress.

Another Congress, not less interesting, is that on Hypnotism, which has been organized under the auspices of Drs. Dumontpallier of Paris, Grasset of Montpellier, Liégeois of Nancy, and Berillon of Paris. The Congress has for Presidents of Honor Drs. Charcot, Brown-Séquard, Azam, Brouardel, Charles Richet, Sombroso. The Congress is International, and will be devoted to experimental and therapeutic hypnotism. The first meeting took place on Thursday the 8th inst., and the Congress will continue in session until Monday the 12th inst. The meeting was well attended, and presided over by Dr. Dumontpallier. The following subjects will be discussed at the meetings: 1. Necessity for forbidding public exhibitions of hypnotism, by Dr. Ladame, of Geneva. 2. Relative value of the different processes intended to produce hypnotism and to increase suggestibility from a therapeutic point of view, by Professor Bornheim, of Nancy. 3. Indications of hypnotism and suggestion in the treatment of mental disease, by Dr. Voisin, of Paris. 4. Application of suggestion in the mental education of vicious or depraved children, by Dr. Berillon, of Paris. 5. Relations of suggestion and somnambulism to the law and to medical jurisprudence. Responsibility of those in hypnotic conditions, by Professor Liégeois, of Nancy. It will be seen that the programme is sufficiently interesting, but it is impossible to give even the summary of the discussions in an ordinary letter.

On Monday the 5th inst. the International Congress of Mental Medicine was opened in the large amphitheatre of the College of France, under the Presidency of Dr. Falret. Drs. Ball, of Paris, and Morel, of Brussels, were elected Vice-Presidents, and Dr. Ritti General Secretary. Dr. Falret read a report on the first question of the programme: Obsessions with consciousness (intellectual, emotive and instinctive). He said that it is not very long ago that the consciousness of a patient's state excluded the idea of a mental malady. However, Esquirol and Baillarger had already published observations of insanity with consciousness. Now-a-days, all physicians admit these singular morbid forms. Certain ideas, certain emotions, certain impulsions, take hold of a patient in an irresistible manner. He knows that they are false, deceiving and not natural, which he wishes to repel. He combats them, but they impose themselves on him in spite of himself. One patient cannot see a razor without wishing to cut his throat, another is beset with the idea of stealing; the latter is at the same time beset with the idea of homicide. These troubles, though varied, have the same character of being recog-

nized so far as concerns the consciousness of the patient and the domination of his will. Heredity here plays a rôle so essential that Magnan designated this form of insanity under the name of hereditary insanity. Others have named it insanity of degenerated subjects. It is remittent, with intervals of appeasement sufficiently long to lead one to believe in a permanent cure. It is never altogether isolated in its symptomatic manifestation, but it is accompanied with anguish, with doubt and varied emotive symptoms. On the contrary, it is never associated with hallucinations, it is not transformed into any other variety of mental aberration, it never ends in dementia, and it is only exceptionally that it is accompanied with the delirium of persecution or that of melancholy. The members of the Congress listened with great interest to the report of Dr. Morel, on the works of the delegates to the International Commission to establish the bases of a good International statistic of mental diseases. Dr. Morel proposed the following classification: 1, mania; 2, melancholia; 3, periodical insanity (a double form, etc.); 4, progressive systematized insanity; 5, insane dementia; 6, organic and senile dementia; 7, general paralysis; 8, neurotic insanity (hystero-epilepsy, hypochondriasis, etc.); 9, toxic insanity; 10, moral and impulsive insanity; 11, idiocy. A. B.

## DOMESTIC CORRESPONDENCE.

### Yellow Fever.

#### *Audi Alteram Partem.*

*To the Editor:*—I have just read a letter in THE JOURNAL for July 27, last, from S. Paulo, Brazil, about the yellow fever in Santos, Campinas, and other smaller places in the same Province, with a great deal of interest and attention, as I am in the position to bear testimony to its correctness, having been all the time of the late epidemic practicing in Rio de Janeiro, which also suffered at the same period; so much so that the fatal year, 1889, will not soon be forgotten there. I was in correspondence with a medical friend in S. Paulo who gave me a very graphic picture of the state of affairs there, and I shrewdly suspect that he is the author of the letter in THE JOURNAL; and as I know and esteem him as a competent observer of rigid impartiality, I think he will be obliged to me for explaining away an erroneous impression he seems to have imbibed from the defenders of Freire's preventive inoculation (or vaccinations, as he himself calls them) against yellow fever.

The paragraph I allude to is as follows: "It is to be regretted that the gentleman who was sent out here by our Government to investigate Dr.

Freire and his method could not have selected this season of the year for his studies, when yellow fever can always be found and Dr. Freire is always at home."

Now Dr. Sternberg was not sent to study yellow fever clinically, he having had ample experience of the disease in question during several epidemics. He went as an expert in bacteriology, and under definite orders, signed by the President of the United States, to study the *results* of the inoculations made by Dr. Freire, and it is the opinion of all impartial people who are familiar with this affair that he did it in a most thorough manner. Besides, *one* typical case of yellow fever would be enough to furnish material for Dr. Sternberg's investigations as to the universal existence of the pathogenic germ of Dr. Freire, and no one will deny that such a case can, unfortunately, be found at all seasons of the year in Rio de Janeiro, and that Dr. Sternberg found more than one case during his stay in Rio, and that he worked jointly with Freire in his laboratory. I, myself, was with him one day in Dr. Freire's laboratory, where I was shown a micrococcus said to be the germ in question, and once again at an apothecary's in Rua Conde d'Eu, when Dr. Freire inoculated three persons in our presence.

That is all, and I think I have said enough to stay opinions on Dr. Sternberg's proceedings until the publication of his forthcoming report, which will be ample and conclusive enough to set at rest this unhappy dispute, which up to to day has exhibited more violence than is admissible in a scientific discussion.

R. CLEARY, A.M., M.D.

Washington, D. C., August 19, 1889.

### Ovarian Cyst, with Extensive Adhesions, in a Patient 80 Years of Age—Recovery.

*To the Editor:*—I send you the report of a case which I think will be of interest to the readers of THE JOURNAL, and hope it may be of use to others in similar cases in forming a favorable prognosis where age seems to contradict any operative procedure that may give the patient a chance of prolonging life.

Mrs. H., 80 years old, native of South Carolina, resident of Edisto Island. First seen by me July 2, 1889. Her weight at that time was 85 lbs., her general health bad. She insisted on my operating at once, strongly against my desire and advice—said life was a burden to her, assumed all the responsibility and preferred death under the operation, rather than to live any longer in her present condition. Four days later I made an exploratory incision in the median line, as usual, and about 6 inches in length. During the progress of the operation this incision was extended to the umbilicus. The entire peritoneal cavity was of a dark crimson hue, but there was no

lymph, pus, or ascitic fluid. The tumor, which was about the size of a foetal head at full term, was found to be firmly adherent to the intestines everywhere, except its upper surface. Not even the slightest space between the tumor and intestines could anywhere be discovered. There was no attachment to the uterus, bladder, or other abdominal viscera. Its enucleation was at once considered; but after separating a portion, in area equal to the surface of the palm of the hand, without discovering any lamination, but with the feeling that I was digging into solid tissues, instead of separating layers, I became alarmed lest I should make matters worse, and desisted. During the progress of the operation the abdominal viscera were protected by frequent applications of soft, warm cloths, wrung out in hot carbolized water. The natural heat of the body was maintained by keeping the temperature of the room at 80° F., and during the latter part of the operation, by also applying bottles of hot water to the patient's extremities. The patient was under chloroform sixty-five minutes.

The shock was great and left her in almost a dying condition; under hypodermatic injections of ether and atropin she rallied. The spray used was listerine 1 to 8, the instruments, sponges, etc., were kept immersed in a hot 2 per cent. solution of carbolic acid. The highest temperature reached was 101.5°, on the third day. The patient on the third night was given a suppository of ¼ gr. of morphia, after that she slept naturally without opiates. The day following the operation, a small quantity of milk was taken and readily assimilated. Nothing but milk and beef-tea was given till the eighth day, when chopped beef and cracker was allowed and well borne. The abdominal sutures, which were of silk, were removed on the sixth day, primary union being perfect, and on the following day the bowels moved naturally.

The patient has recovered and at the present time, August 10, 1889, writes me that she eats and sleeps well and is in good health, weighing now 115 lbs.

In presenting this contribution to the profession I give no excuse, as the case seems to me, at least, of great importance, first as to the extreme age of the patient, and secondly to the almost fatal shock sustained, which as by a miracle she slowly rallied from and ultimately recovered. Respectfully,

THOS. LEGARÉ, M.D.

Charleston, S. C., August 19, 1889.

#### The Pekin University and its Medical Department.

To the Editor:—I observe in a recent number of THE JOURNAL a statement that a University under British tuition has been established at Pe-

kin, China, with a medical department in working order.

The Pekin University has been organized in that city for a number of years, under the direction of the Rev. Dr. L. W. Pilcher. The medical department has been in active operation for several years and is doing excellent work. This institution, however, is under American control, and the majority of its faculty are Americans.

JAS. E. PILCHER, Asst Surg. U. S. Army.

Governor's Island, New York City, August 22, 1889.

## NECROLOGY.

### Death of Dr. Turner.

Dr. J. Edward Turner, the Founder of the New York State Inebriate Asylum, at Binghamton, N. Y., died at his home in Wilton, Conn., on the 24th of July, at the age of 67 years, after a short but painful illness.

Thoroughly impressed with the idea that *inebriety is a disease* needing medical treatment, he gave his life to the work of winning over public opinion, and the coöperation of scientists and the thoughtful philanthropists of his age, to the treatment of the inebriate as a sick man, and not as a criminal.

The Binghamton Asylum was founded as the result of his individual effort, and though for a while diverted to other uses at the time of his death, he was its sole proprietor, and had he lived it would doubtless been the ambition of his life to restore it to its original purpose.

He was in its fullest sense a philanthropist, and only recently is the medical profession ready to accept and utilize many of the tenets which he began to promulgate nearly fifty years ago.

## BOOK REVIEWS.

THE DIAGNOSIS AND TREATMENT OF EXTRA-UTERINE PREGNANCY. By JOHN STRAHAN, M.D., M.Ch., M.A.O. (Royal University of Ireland). Jenks' Prize Essay of the College of Physicians of Philadelphia. Philadelphia: P. Blakiston, Son & Co. 1889.

This is a valuable contribution to our knowledge of a very interesting subject, and well merits the prize which has been awarded it. The question of diagnosis before rupture, at the time of rupture, during the first three months, and at or about the viable period are very fully discussed. Considerable space is also devoted to the question of differential diagnosis. Among the concluding remarks on diagnosis the author says, "Those

who diagnose or fancy they diagnose early extra-uterine pregnancies depend on two things, principally, viz., the presence of all the most important signs of ordinary pregnancy and the interruption of menstruation, if only for a period or two, of course with the presence of an extra-uterine tumor. Now the ordinary signs of pregnancy and menstrual suspension may both be absent, in which case they are apt to fail most disgracefully."

The results of rupture are one of two things, either an *intra*- or an *extra*-peritoneal hæmatocele. In the latter case the rupture is so situated that the blood is poured out between the layers of the broad ligament and the effusion is confined in some degree; while in the *intra*- variety the bleeding, which is limited only by the peritoneal cavity, is sure to be fatal, if not immediately, at least after a very short time.

The killing of the fœtus by electrical methods or by injections of drugs, etc., suggests an interesting consideration, and the author observes that, "As in intra-uterine pregnancy the death of the ovum is the great cause of abortion, may not our killing the fœtus bring on efforts at its expulsion, the false abortion which ends in rupture of the tube? In fact, may not the killing of the fœtus promote the very accident we are so anxious to guard against?" Among other considerations which the destruction of the fœtus gives rise to, is, whether or no the placenta continues to grow after the fœtal death. This is a controverted point, though Tait and others do believe in the continued growth of the placenta.

In cases of doubtful diagnosis, the fœtus being dead, a trocar or aspirator may be used to draw off some of the liquor amnii, both to confirm the diagnosis and relieve the pressure within the tumor, though "unless it has been decided to operate immediately for the removal of the fœtus, the use of the trocar is utterly unjustifiable. But very few women have long survived its use."

In the forty-two operations Tait has done for hæmorrhage and abdominal collapse, a name introduced by Barnes to denote that group of symptoms which follow rupture, he has had only two deaths, a mortality of 4.7 per cent.; and it is safe to say that every one of these would have died under any other treatment.

A bibliography of the subject is appended to the volume, making it very convenient for those who wish to study further.

A MANUAL OF INSTRUCTION FOR GIVING SWEDISH MOVEMENT AND MASSAGE TREATMENT. By PROF. HARTVIG NISSEN. Philadelphia and London: F. A. Davis, Publisher. 1889.

A small work of 128 pages, illustrated by 28 woodcuts. According to the author this is probably the only manual on this subject in the English language which gives any information how

to apply the treatment in different diseases. It is the object of the handbook to give directions sufficient to enable the physician, or an operator under his direction, to apply the "movements" in the sick-room without the aid of apparatus.

The value of this mode of treatment should be recognized and neither prejudice nor ignorance should stand in the way of its adoption when it can be beneficial.

THE PHYSICIAN HIMSELF AND THINGS THAT CONCERN HIS REPUTATION AND SUCCESS. By D. W. CATHELL, M.D. Ninth Edition, Revised and Enlarged. Philadelphia and London: F. A. Davis, Publisher. 1889.

If the change from the old-fashioned preceptorship had its immense advantages to medical education they were not, however, wholly unqualified; where much has been gained by the modern system, still something has been lost. What that loss is the present volume indicates better than any brief work can. That peculiar gift of professional tact and talent the author has tried to make conceivable to the reader. It is these qualities, eminently essential to the successful practice of medicine, and usually best acquired by associating with and observing those who possess them, that the preceptor of former times conveyed to the student under him by a power of personality and dignity of bearing which we venture to say few schools are capable of exerting over their students. The success of this work has been such that a ninth edition is before us. The author has in fact made accessible to the young graduate many valuable rules of conduct and words of advice, which as the custom is now-a-days remain untaught, because in the very nature of things we cannot endow a corporate body (a medical faculty) with that personality which will enable it to teach a philosophy of conduct that shall give a distinguishing dignity to all who acquire their knowledge under it.

Such principles the young physician of to-day must acquire for himself, guided by his own natural instinct, observing where he can and reading where he can. An opportunity for such to read with profit is here given.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS, AUGUST, 1889. William Wood & Co., Publishers.

This number contains monographs upon: "The Treatment of Syphilis at the Present Time," by Dr. Maximilian von Zeissl. "The Treatment of Inebriety in the Higher and Educated Classes," by James Stewart, B.A., and a "Manual of Hypodermic Medication," by Drs. Bourneville and Bricon. The latter is the most extensive work of the kind which we have seen. It contains more than 125 different drugs whose administration

and therapeutics are taken up from the hypodermic standpoint, and arranged alphabetically. For instance, mercurial medication by the hypodermic method receives about 15 pages. The mode of preparing and using the albuminate and peptonate of mercury for injection is fully given. Quinine occupies 11 pages, and the discussion of the other more important drugs is taken up under the heads of Physiological Effects, Local Effects and Therapeutics. There are included many new drugs which are commonly not employed hypodermically, and of which even the therapeutics is not well known, *e. g.*, arbutin, hypnom, kairin, solanim, sparteine, arseniate of strychnine, thallin, urethan, and others. While many unusual drugs, and ones of questionable value, are given a place in this manual, those of well-recognized value receive full and satisfactory treatment.

TRANSACTIONS OF THE AMERICAN ORTHOPEDIC ASSOCIATION. Vol. I. Published by the Association. 1889.

The first volume of this society is a promising one, containing as it does, some twenty-four papers and the discussions which follow each. It will be read with interest by surgeons, and particularly those who devote themselves to this department.

Dr. E. H. Bradford has a valuable communication on the "Treatment of Club-Foot," to which is appended a tabular record of 101 cases, giving results and detailed notes in illustration. A study of these cases is used in the attempt to substantiate the following statements:

1. "That the cases of infantile club-foot can, as a rule, be thoroughly and efficiently treated without tenotomy by mechanical correction, and mechanical retention alone. Tenotomy, however, is an aid even in infantile cases."

2. "That in older cases tenotomy aids the correction, and is not injurious in the permanent result."

3. "That, as a rule, resistant cases of the severest type can be corrected without tarsal osteotomy, by forcible rectification."

4. "That in exceptional cases of resistant club-foot, tarsal osteotomy may be needed for perfect rectification, and is not only justified, but may be indicated in exceptional instances."

Some interesting points were developed in an essay entitled, "An Experimental Study of Fixation and Traction in the Treatment of Hip-Joint Disease, with the Description of a Splint," by Robert W. Lovitt. American orthopedic surgeons generally agree that the best results are to be obtained by the continued use of the long traction splint. While on the other hand, English surgeons do not take the same view, holding that it is impossible to maintain extension with such splints as those described by Davis, Taylor, Sayre and others; also that they

do not furnish adequate fixation of the joint. A series of experiments were undertaken to determine how much fixation is afforded by the ordinary Taylor hip splint using one perineal band, when walking is attempted; and also how much fixation was dependent upon extension. A pencil attached to the apparatus registered mechanically any motion of the joint and a dynamometer measured the number of pounds exerted in extension. The apparatus was first tried in an ankylosed hip, and of course, showed no motion, then upon those who had hip disease, and those who were sound. An amount of motion equal to from 15° to 40° was recorded, and this seemed neither increased nor diminished by altering the extending force. The author does not undervalue extension, but his experiments seem to show that it does not contribute to fixation in any perceptible degree. Former investigations have shown that the articular surfaces are not in the least separated by any ordinary amount of traction, therefore the only explanation of the benefit to be derived from extension rests upon the fact that force thus applied overcomes muscular spasm, and thus diminishes the pressure at the points of contact within the articular capsule. At least the *modus operandi* of this agent is open to further study.

We might cite portions of many other papers which deal minutely and scientifically with their various subjects, but those who are interested can more profitably consult for themselves.

SURGICAL TREATMENT OF DISEASES OF THE BRAIN. By PROFESSOR E. v. BERGMANN. 1889. Published by A. Hirschwald, Berlin. Review in *Berliner Klinische Wochenschrift*, July 8, 1889, by W. Koerte.

The author advises to operate only in cases in which a definite diagnosis can be made. In cases of hernia of the cerebrum he advises tying of the pedicle and removing the tumor. No great harm is noticed from the loss of brain tissue in these cases. There is less danger in the operation for encephalocele than in that for hydrocephalocele, because in the latter the danger from hydrocephalus continues after the operation. In the occipital region cephaloceles are amenable to surgical operation only if they are small or if they are pure meningoceles. Deeply seated abscesses are considered at length. They should be opened and drained whenever positively diagnosed. The diagnosis depends chiefly upon the etiology. The following causes are given: traumatic injury to the hard or soft covering of the brain, or suppurative inflammation of some skull bone, usually the temporal, in connection with otitis media purulenta. Extensive suppuration, notably of the lungs, may be followed by metastatic abscesses of the brain. They may also depend upon tuberculosis. In these two instances

nothing can be hoped from surgical aid. In the other much depends upon an early diagnosis.

The important symptoms are: 1, those caused by the accumulation of pus (temperature, general condition); 2, compression caused by the growth of the abscess; 3, regional affection, this is especially marked if the abscess is near the motor region of the cortex, but the absence of regional affection has no absolute weight if the other symptoms exist. Von Bergmann reports eight cases of successful diagnosis and treatment. All of these cases followed chronic purulent inflammation of the middle ear. He warns very strongly against opening the skull unless a definite diagnosis has been made.

The author is much less hopeful regarding surgical relief for tumors of the brain. The tumor may be diagnosed but it may be difficult to locate it definitely. It is also impossible to determine whether it can be enucleated and, if this is possible, whether or not it will recur. V. Bergmann quotes the very important collection of cases by H. White, which shows that of the 100 cases nine might have been relieved by surgical operations, but of these seven could not have been diagnosed on account of their location.

In cases in which a tumor cannot be located definitely, exploratory trephining is not justifiable. Aside from the possibility of not finding the tumor there are two great dangers, viz.: hæmorrhage and secondary œdema. All of these principles are confirmed by clinical histories of cases observed by himself and others. In seven cases intracranial tumors were diagnosed, located and removed. Three cases died after the operation, one from recurrence after three months, and three cases recovered permanently. Of eighteen cases eight died after the operation, two from recurrence, and eight recovered. In epilepsy operations are allowable only in clearly marked cases of Jacksonian, *i. e.*, epilepsy due to cortical irritation. In these cases v. Bergmann advises excision of the diseased portion by Horsley's method.

In the last chapter puncture and aspiration of the ventricles for relief of intracranial pressure is considered. A patient suffering from long continued headache after a fall was relieved by v. Bergmann by the aspiration of blood from the ventricle. In a case of tubercular meningitis only symptomatic benefit was achieved. The book is complete and a valuable addition to the literature.

## MISCELLANY.

EDWARD CHADWICK, a distinguished sanitarian, has said that he could construct a city which would give any desired death-rate from five, or possibly less, to fifty or more in 1,000 inhabitants annually. This has the endorsement of the President of the Health Department of the British Social Science Association, who, at an annual

meeting some years ago, expressed his unqualified belief in the feasibility of Mr. Chadwick's proposition. If this is true, and it comes from very high authority, the responsibility of municipal authorities and boards of health is measured through a wider range than is generally supposed. With a death-rate ranging about twenty-five per 1,000, health officials should multiply their diligence by about five to secure the minimum death-rate.—*The Sanitary News*.

THE faith-cure doctor took the hand of his patient, and looking into his eyes, said: "I can cure you." Patient—"Are you sure?" "Very sure. All you've got to do is to believe. Just believe you're cured. That's all." "All right; I'll try it. Good day." "Hold on a minute, my man. Didn't you forget something?" "What?" "The fee, I charge a dollar a visit." "Oh, yes. Well, believe. All you've got to do is to believe I've paid you and it'll be all right."

ADDRESSES.

RECENT ADVANCES IN THE TREAT-  
MENT OF DISEASES OF THE  
SKIN.

*Read in the Section on Dermatology and Syphilography at the Fortieth  
Annual Meeting of the American Medical Association held  
at Newport, R. I., June, 1889.*

BY L. DUNCAN BULKLEY, M.D.,  
OF NEW YORK,  
CHAIRMAN OF SECTION.

*Gentlemen* :—In opening the Second Session of the Section of Dermatology and Syphilography of the American Medical Association, I must first express my thanks publicly to the gentlemen who at the last session so kindly called me the second time to preside over your deliberations, an honor which was as unexpected as it was gratifying. I must also congratulate you, and, I believe, the profession at large, upon the interest which the Section has developed, and express the hope that by its means the large and important field of study and practice which is here represented may be simplified, so that diseases of the skin may no longer represent the *terra incognita* which they have sometimes been considered by those inexperienced therein.

As was remarked last year, on opening the session, the Section is organized for work in the line of *practical* dermatology, and as a Section of the American Medical Association it should be attended by members who are not dermatologists, and subjects should be presented which are of general and practical interest and value to the general practitioner if we would seek to give the widest usefulness to our Section.

With this aim in view we have this year, as well as last, prepared a "question box" into which any one may drop a written slip regarding any subject upon which he would like aid or information from those present, or on which may be proposed subjects for future discussion. It is earnestly requested that this method of securing an interchange of ideas be utilized to as great a degree as possible; an hour has been set apart on the second day for answering such questions, and further time can be taken later if necessary; if freely used this plan might be made the means of

developing very interesting practical matter which would not otherwise be reached.

The general topics assigned for discussion at this session, namely, "The Treatment of Tinea Tonsurans," and "The Indications for and Duration of the Treatment of Syphilis," are, it is thought, subjects which are of very considerable practical and general interest. While pathological considerations, and those relating to rare and peculiar diseases of the skin may be of a certain advantage here, and may more or less find a place in this Section, it is hoped that more common matters, which shall be of use in general practice, may in the main be presented, while the more abstruse and difficult subjects shall be left for the consideration of those whose attention is wholly or largely given to this branch, in the American Dermatological Association.

By the rules of the American Medical Association it is the duty of the Chairmen of the various Sections to give an address upon the advances which have been made in the departments of medicine represented by the Sections, and to bring to their attention such matters as may be considered of interest and profit. In accordance with this rule I beg now to direct your attention for a short time to the subject of "Recent Advances in the Treatment of Diseases of the Skin." Inasmuch as this is the first time that this subject has been presented before the Section, we have no date from which we may reckon the *recent* advances in the treatment of diseases of the skin; I have thought it best, therefore, not to confine our considerations to any specified time, but to look over the field a little broadly, and to take account of stock, as it were, endeavoring to discriminate between the good, bad, and indifferent of the more recent so-called "advances" in this department.

It is a constant remark among those acquainted with the subject, that the need is not so much for new remedies, in dermatology, or indeed in any department of medicine, as it is of a better knowledge of the true value and mode of application of those means of combatting disease which we now possess. While the question is repeatedly put to one occupied in any special branch, "What is the newest or best remedy for this or that complaint," he is obliged just as frequently to reply

that there is no one remedy or plan of treatment which is wholly satisfactory in any particular disease, or which will reach every case; and if, perchance, a suggestion is made of any particular drug or method he feels that the chances are very great that there will be some error or some failure to use the remedy correctly, and that the ultimate result is very doubtful. In no department of medicine is this true to a greater extent than in diseases of the skin, and yet nowhere can we see more brilliant results, the accuracy and truthfulness of which cannot be denied, because plainly visible to all, than in the department of dermatology.

The first advance, therefore, to which I would call attention in the treatment of diseases of the skin is the recognition of the fact on the part of those acquainted with the subject that accuracy of diagnosis is essential to success in the treatment of this class of affections, and intelligence in the application of remedies can alone insure results which are not disappointing. I would feel like apologizing for such an apparently self-evident statement, were it not that a considerable experience in consultations with other physicians has made me think that too little care is often spent in studying this class of cases, and in recognizing all the features requiring attention, both as regards the local affection and the constitutional condition of the patient. If the same care and thought were expended upon certain cases of skin disease which are readily given to obstinate or obscure diseases of other organs there would be less difficulty in their management. The time has passed when a patient afflicted with an affection of the skin should at once be given arsenic internally and zinc ointment externally; and then, in the event of probable failure, that he should be given mercury or iodide of potassium, under the suspicion that perhaps there may be some "taint;" and then in the further event of a failure of these plans, that he should be either left to suffer, or be informed that it would be dangerous to cure the skin trouble lest "the disease might strike in." There is much in the practice of dermatology which the general practitioner may readily grasp and use, if only sufficient care and thought be given, and, in my judgment, as remarked before, there is much less need of new remedies than there is of a careful, proper and widespread knowledge of the means already known, and their intelligent use.

The second point to which I would call your attention is, that while accuracy of diagnosis is the first essential to success, it is almost equally important to consider well and appreciate thoroughly the particular condition or stage of the eruption under consideration, and, knowing the action and effect of each remedy to use it accordingly. The same measure advised for a certain disease will act entirely different under different con-

ditions and at various stages of the complaint, so that one constantly sees harm done from harsh remedies when those of a soothing nature were required, and mild measures are often uselessly employed when those of a stimulating character were demanded. As a corollary to this we learn that even the new remedies and methods of treatment advanced will often fail of success unless it is known exactly at what stage or condition they were employed and in what manner they acted.

One more general remark may be added and we will pass to consider some of the more recent advances in dermatology. It is this. Not only do remedies and measures act differently in different persons and under diverse conditions, and in different stages of a disease, but their action may be modified, aided or retarded by a number of influences which are not always thought of, such as diet, hygiene, and the effect of other remedies, internal or external. Therefore, in the use of any newly-recommended measure all other proper adjuvants are to be employed and all antagonistic elements are to be removed; and as a corollary to this we learn that new remedies are not always to be judged negatively by an apparent failure, nor, on the other hand, can we always conclude favorably of the effect of any special agent unless all other elements bearing on the case are also duly considered.

With this much of preface we may consider some of the therapeutical elements which have in recent years been introduced into the practice of dermatology. Time will not permit of a full consideration of all that might be mentioned with advantage, much less of the many which have been brought forward whose claims have not been fully substantiated. Indeed much even that might be of interest and value must be left for my successors in office, who will, no doubt, consider and present the subjects with abler pens than mine.

First, among the advances in dermatology during recent years to be mentioned should be the *mechanical therapy* of diseases of the skin, which, when properly employed, aids very greatly in the management of many conditions which had heretofore proved very rebellious; of this there are several forms. The curette is very serviceable in the treatment of lupus, also in removing small epitheliomata, warts and excrescences, and it may sometimes be used with advantage on chronic patches of eczema, also psoriasis.

The cutaneous punch, as introduced by Keyes<sup>1</sup> is also of value in removing small circular portions of skin, the seat of moles and the like, also powder stains, and likewise in taking sections of diseased tissue for microscopic examination.

The cutaneous lance plays an important part in the treatment of acne, and together with the

<sup>1</sup> Keyes, Jour. Cutaneous and Genito-Urinary Diseases, Vol. v, 1887, p. 98.

comedo extractor, will accomplish more for some cases of this disease than weeks or even months of other treatment can effect without them.

Multiple scarification, performed either with a scalpel or an especial knife made for the purpose, with the cutting surface on the end, or with the many-bladed knife of Squire, serves an excellent purpose in certain cases of lupus, and will also yield good results in some nævi, and in rosacea. The large veins of acne rosacea, especially on the nose, may be removed by slitting them up carefully and burning the track of the vein with a point of nitrate of silver. They may also be successfully obliterated by electrolysis.

Electrolysis now plays a considerable part in dermal therapy, and in some conditions yields brilliant results. Its use, now so common, in destroying superfluous hairs, need but be mentioned, as is well known, it offers about the only method of permanently removing this blemish, which often proves such a serious annoyance or distress to those thus afflicted. The only other method known to me is one which I devised and presented some years ago, namely, that of boring out each hair follicle with a three-cornered needle, dipped in carbolic acid; when well performed this is fully as successful as electrolysis, and is preferred by some patients who have had both methods used on them.

Electrolysis is likewise of value in destroying pigmentary and hairy moles, and nævi of various sizes, as also in producing the absorption of tumors. The galvanic cautery also plays an important part in the treatment of some affections, the end, however, being the same as that obtained by the actual cautery and by Pacquelin; but with the galvanic cautery more delicate work can be done, and Besnier has devised a considerable variety of shapes for the knives, some of them having a number of fine points, heated by electricity, for the treatment of nævus and other conditions. The value of the galvanic current, variously applied, must also be reckoned among the advances of recent years. It is most valuable in checking the pain accompanying and following herpes zoster, and there is some evidence that it tends to arrest the progress of the disease; it is valuable in relieving the pain in dermatolgia, and to a certain extent will control pruritis. Galvanization has also been reported on favorably in connection with other diseases of the skin, notably eczema, it being used in the form of general or central galvanization. Faradization has also been recommended in acne rosacea, but is of doubtful value.

Perhaps there are no remedies to which more attention has been called of late than ichthyol and resorcin, largely through the instrumentality of Dr. Unna, of Hamburg, and time sufficient has now elapsed since their first introduction to allow of judgment regarding their true merits, for quite contradictory reports have appeared con-

cerning them. They are placed by Unna as reducing agents, drawing oxygen from the tissues, and altering the corneous layer of the skin. They are by no means indifferent substances, but while capable of doing more or less good when properly used, they are irritating in many conditions, and in my experience, as also that of some others, they have not fulfilled the expectations excited by Unna's original contributions to the subject.

Ichthyol should always be used weak at first, the strength being increased according to the effect produced; 2 per cent., either in water or ointment, is strong enough to begin with, and rarely will more than 5 per cent. be well borne, at any rate on American skins. As a lotion, 2 to 3 per cent. in water, it certainly often exercises a remarkable effect on ulcers of the leg, they being kept wet with it all the time, the dressing being covered with a thickness of woolen blanket (but not rubber or oil-silk), to prevent too rapid evaporation. It is sometimes well at night to substitute an ointment, with 2 or 3 per cent of ichthyol and a little zinc oxide. In certain moist eczemas about the folds of the body, a light bathing with a weak, 2 per cent. ichthyol lotion, followed by a calamine and zinc lotion, will give much better results than the latter alone. In certain cases in eczema in infants the effect produced by a thorough and continuous use of a zinc ointment containing 20 grains of ichthyol and 15 or 20 of salicylic acid, is certainly remarkable, and undoubtedly much greater than from either the zinc ointment alone, or when combined only with the salicylic acid.

Time does not permit of a fuller consideration of ichthyol in this place, but enough has been said to show that it is an agent of some importance, capable of doing harm when used too strong, and of moderate value in allaying acute erythematous conditions of the skin.

Resorcin, which has been spoken of much in connection with ichthyol, is said to have much the same effect, but its action is more uncertain, and its use more restricted. It is undoubtedly a parasiticide, and forms a very cleanly and pleasant application in tinea vesicular, used in solution from 3 to 5, or even 10 per cent. in water with a little alcohol and glycerine. It is also of value in tinea circinata and maginatum, and it is claimed that a strong ointment, from 3 to 10 per cent., will act most favorably in tinea sycosis. Resorcin is also serviceable in pityriasis capitis, used in a 3 to 5 per cent. solution with alcohol and castor oil. In seborrhœic eczema it also acts very well in a strength of 3 per cent., with zinc ointment. In psoriasis it may be used considerably stronger, even up to 10 to 20 per cent. in ointments.

Resorcin certainly seems to have considerable effect upon the sebaceous glands, and is useful in

many of the forms of acne. Used in an alcoholic and watery solution, of from 2 to 5 per cent., it checks the oily secretion so common on portions of the face, and as an addition to lotions containing sulphur it often aids greatly in the treatment of acne. It must not be forgotten, however, that resorcin may prove very irritating if used in too strong a proportion—3 to 10 per cent. is quite sufficient—and also that it often produces a discoloration of the epidermis, which may take some little time to wear off.

Unna has also, during the few past years, written much concerning the uses of various ointments made into the form of plasters, by making them thicker and more sticky, and then pressing them upon and into the meshes of muslin: these so-called "pflaster-mulle" have been imported from Germany but little, and are difficult to obtain. They are made to contain zinc, tar, naphthol, chrysarobin, ichthyol, salicylic acid, and other ingredients. These plasters serve a certain valuable purpose in keeping a fixed dressing in localities where it would otherwise be difficult to retain an application, and also by the maceration afforded aid in removing disease; on the other hand, they often prove too drawing, and unless the medicament is very bland, much inflammation may thereby be set up.

In the same line of therapy may be mentioned the "dermatological plasters," now prepared and offered by several firms in this country, which at times serve an excellent purpose; they are mostly made up with rubber plaster, and often prove too heating and drawing, and can hardly be considered the equivalent either of the "pflaster-mulle" or of proper ointments well spread on lint and kept in place by suitable dressings. Among these new plasters may be found those containing very many of the more common and newer drugs used in dermatology. I cannot speak personally regarding very many of these, but some of them prove at times of very great service. Thus, in thickened patches of eczema, about the hands and feet especially, the salicylic acid plaster, 10 or 20 per cent., will promote absorption and greatly reduce the thickening; those with zinc and tar, each 10 per cent., are also valuable in eczema, and those with 10 per cent. of chrysarobin act well in psoriasis; all are familiar with the value of plasters containing mercury in reducing the late lesions of syphilis.

Attempts have been made in other directions as to the means of securing fixed dressings on the skin, and various preparations have been brought forward to hold the medicament in solution or suspension, while it is painted over the affected surface. The use of collodion, made flexible with castor oil, has long been known, and this often serves a most excellent purpose when containing from 3 to 5 per cent. of chrysarobin, or pyrogallie acid, and as much salicylic acid; io-

dine may also be successfully applied in this manner. Gutta-percha dissolved in chloroform, the liquor gutta-perchæ of the Pharmacopœia, or traumaticine, as it has been called by the trade, affords another admirable method of affixing medicaments to the skin; any desired substance, oxide of zinc, bismuth, tannin, chrysarobin, or preparations of mercury may be suspended in it, and made to adhere to the skin thereby.

Another mode of making fixed dressings is that known as glycerine jelly, made by boiling one part of gelatin with three or four of glycerine, and a little water if necessary to make a gelatinous mass. The various ingredients desired are incorporated with this while hot, by stirring, generally from 5 to 10 per cent. being added, together with a little carmine to give a flesh tint if it is to be used on exposed surfaces. This forms a bland dressing, and with zinc or bismuth serves well to protect large surfaces; it will not adhere when there is moisture exuding, but on dry, scaly eczema, in some cases of lichen planus, and pityriasis rosea, it forms a serviceable dressing. Carbolic acid, camphor, or cocaine may be added to relieve itching. It is applied by placing the jar containing the jelly in hot water, when the liquefied substance can be freely painted over the affected surface, forming a smooth protecting coat as it cools.

Considerable attention has been called to lanolin during the past few years, largely, it is feared, on account of the vigor with which it has been pushed in a mercantile way. Its merits have been pretty well tested, and it may be stated that it has not fulfilled the high expectations which have been raised concerning it; it has its value and its applications, but they are limited, and it will undoubtedly take its proper place among the remedies which are of value in the treatment of diseases of the skin. It does not answer alone as a basis for ointments, but when combined with other fatty ingredients, in about 25 per cent., it often aids in keeping the skin soft and pliable, when without it the oily matter would disappear and leave the surface harsh. It has been advocated largely on account of its supposed power of inducing absorption of the medicament which it contained; if this power existed in this substance alone, it would not recommend it for universal use, for in much of dermal therapeutics the object is not to secure absorption of remedies, but to act on the outer surface. It would surprise many to see how very little it is used by those engaged in the practice of dermatology.

Another addition to the class of fatty bases for ointments which has been brought forward of late years, is found in the various preparations made from petroleum, notably, vaseline, cosmoline, and albolene. All are familiar with the wide range of applicability of these substances, and the service which they have rendered is un-

questionably very great, and they could be illy spared from the Pharmacopœia. But it is proper here to raise a word of caution against their too common use as a basis for ointments, it being even proposed, I am informed, to make it the official basis of ointments in the coming revision of the Pharmacopœia. The New York Dermatological Society has already taken strong action in opposition to this suggestion, and every one who has carefully tested the subject will readily see that it is far inferior to other substances for this purpose, certainly in the large proportion of instances. When it is desired to lubricate the surface, as in pityriasis, rubra and many dry and scaly conditions of the skin, nothing better can be desired; and as an excipient, to convey carbolic acid, or other anti-pruritic remedies, to the skin, it answers perfectly. But when it is desired to form a protective covering, which shall hold a medicament in contact with the skin for some time, vaseline and cosmoline are found far too soft, and even albolene does not seem to afford the "body" desired for an effective ointment, such, for instance, as is found in good diachylon ointment made after Hebra's formula.

Here I must speak again for the ointment which I have often mentioned as preferable, in my experience, to all others, and which I invariably use in compounding prescriptions, namely: the unguentum aquæ rosæ of the pharmacopœia. This is composed of almond oil, spermaceti and white wax, with considerable water, and is far more grateful to the skin than lard, and of a consistency which combines best with very many substances. Brief mention may be made of some single substances which have come into pretty general use in dermal therapeutics.

Salicylic acid has been mentioned incidentally several times. It is a valuable addition to our armamentarium, but requires some care in its use. It has a drying effect on the skin, and the addition of 2 or 3 per cent. of it to various ointments will often increase their effect greatly, though sometimes it proves irritating. Combined with hair tonics, in a strength of from 3 to 5 per cent., it acts excellently in cases where there is an oily seborrhœa; dissolved in alcohol and water, 10 to 20 per cent. solution, it is an efficient parasiticide, and incorporated with oxide of zinc, a drachm each to an ounce of powdered starch, it is very efficient in checking excessive perspiration, in the axilla and elsewhere.

Chrysophanic acid, or chrysarobin, as it is now called, is well known to the profession from the remarkable power which it has in dispelling the lesions of psoriasis. When it is desired to remove the eruption quickly, regardless of all else, no agent will accomplish this as quickly as this drug, properly used, but, on the other hand, the disadvantages attending its use in the way of staining the skin and clothing, together with the intense

inflammation which it occasionally sets up, has greatly restricted its use, in private practice at least; personally I use it but little, and then mainly in the form of paint, with collodion or gutta-percha, as before alluded to.

Pyrogallic acid has to a certain extent taken the place of the chrysarobin, but it is less efficacious in psoriasis. Its effect in epithelioma, however, is often quite remarkable, and the powdered acid sprinkled freely on a small epithelioma will often quite alter the diseased action, and ensure healing.

Anthrarobin has also been brought forward as a substitute for chrysarobin, and appears to have a marked effect upon psoriasis. Used in a 10 per cent. ointment it removes the eruption almost as quickly as chrysarobin,<sup>2</sup> and without producing inflammation, or staining as much as the latter. Alkali baths increase its action.

Naphthol has attained considerable reputation from its pronounced value in the treatment of scabies, a 10 per cent. ointment sufficing to remove the disease with little trouble. It is also serviceable in psoriasis, in 15 per cent. ointment, and in seborrhœa and in some other affections.<sup>4</sup>

Two or three antipruritic remedies may be mentioned before bringing this hasty sketch to a close. Menthol in from 5 to 15 per cent. solution, with a little alcohol and glycerine and water, often proves a most serviceable means of allaying itching. Cocaine, from 5 to 10 per cent. in ointment or solution, is also a remedy of value in certain cases. It is also valuable in connection with epilation for parasitic diseases of hairy parts, used either in solution, or in connection with the ointment applied it will very greatly diminish or entirely obviate the pain attending this operation. Campho-phe-nique, a newly presented remedy, composed of camphor and carbolic acid, often proves efficient in pruritus; a drachm to the ounce of vaseline, or perhaps a little stronger, will often give complete rest to an intolerable itching.

In this attempt to direct attention to some of the more recent additions of value to our dermal therapeutics, I have confined my attention entirely to local treatment, for here it is that the greatest advances have been made, or rather those which are most clearly demonstrable. But I cannot close without again throwing out the suggestion that this is by no means all of dermatology, and he will succeed but poorly who relies alone or mainly on local measures. While it is of the highest importance that these be proper and suitable, it is none the less essential, to real and permanent success, that all elements which contribute to the end, as diet, hygiene, and internal medication, should be used intelligently and persistently.

Again I feel like apologizing for the plainness

<sup>2</sup> Bronson. *Journal of Cutan. and Genito-Urin. Diseases*, November, 1888, p. 409.

<sup>4</sup> Van Harlingen. *Amer. Jour. Med. Sci.*, October, 1883, p. 479.

of my speech, and the urgency with which I press this matter; but my apology is only that experience has so often shown me that failure more commonly comes from not perfectly grasping and considering all the elements bearing upon skin cases, than from the lack of proper remedies to meet diseased conditions, that I cannot refrain. The number of new remedies and measures which have been proposed and advocated since I first took up this branch of medicine, twenty years ago, is far greater than could be imagined by one who had not specially watched the subject, and even a brief recital of them might occupy most of the time of our Section, and yet very few of them have stood the test of time and experience, and still fewer of them have obtained a wide and practical recognition, and are now employed.

I would not, of course, discourage attempts to make therapeutic advances in dermatology, but I would only throw out the suggestion of Holy Writ, both to those proposing and those accepting novelties in this department of medicine, "Prove all things, hold fast that which is good."

## ORIGINAL ARTICLES.

### THE MEDALS OF BENJAMIN RUSH, OBSTETRICIAN.

*Read at the Fortieth Annual Meeting of the American Medical Association, held at Newport, R. I., June, 1880.*

BY HORATIO R. STORER, M.D.,  
OF NEWPORT, R. I.

Recently, during researches relative to a paper upon the medals, jetons and tokens illustrative of the science of medicine, at present appearing in the *American Journal of Numismatics*, I learned of a gold medal conferred by the Society of Medicine of Caen, France, upon the late Dr. Jean Charles Faget, of New Orleans, a graduate of the University of Paris, Chevalier of the Legion of Honor, and distinguished as an author in various departments of medicine.<sup>1</sup> With the impressions of this medal that have been kindly sent me by Dr. Faget's family, I have received copies of a portion of his works. Among them is an interesting brochure, published at Paris by the Baillières, entitled, "L'Art d'apaiser les Douleurs de L'Enfante-ment" (The Means of Assuaging the Agony of Parturition).

#### THE CLAIM OF RUSH TO THE TITLE OF OBSTETRICIAN.

In this memoir, Dr. Faget quotes a striking statement by the most eminent, perhaps, of American physicians, Dr. Benjamin Rush, of Philadelphia, for many years professor of the institutes

and practice of medicine and of clinical practice in the University of Pennsylvania. In discussing the symptoms of labor, and as if directly anticipating and answering in advance the objections that were to be urged half a century later in his own city, by the celebrated Dr. Charles D. Meigs, Dr. Rush had said: "By some divines these symptoms, and particularly pain, have been considered as a standing and unchangeable punishment of the original disobedience of woman, and, by some physicians, as indispensably necessary to enable the uterus to relieve itself of its burden. By contemplating the numerous instances in which it has pleased God to bless the labors and ingenuity of man, in lessening or destroying the effects of the curse inflicted upon the earth, and by attending to the histories of the total exemption from pain in child-bearing that are recorded of the women in the Brazils, Calabria, and some parts of Africa, and of the small degrees of it which are felt by the Turkish women, who reduce their systems by frequent purges of sweet oil during pregnancy, I was induced to believe pain does not accompany child-bearing by an immutable decree of Heaven." And again: "I was encouraged (in this) by having known delivery to take place, in one instance, during a paroxysm of epilepsy, and in another during a fit of drunkenness; in both of which there was neither consciousness nor recollection of pain."<sup>2</sup>

The notable passage referred to above as reproduced by Dr. Faget, in his French monograph, is the following: "I have expressed a hope in another place that a medicine would be discovered that should suspend sensibility altogether, and leave irritability, or the power of motion, unimpaired, and thereby destroy labour pains altogether."<sup>3</sup>

The "another place" to which Rush here makes allusion is a letter dated May 12, 1802, to Dr. Edward Miller, entitled "On the means of lessening the pains and dangers of child-bearing, and of preventing its consequent diseases." In this, when speaking of cases "where the absence of throes and the slow progress of delivery indicate a deficiency of muscular irritability in the fibres of the uterus," Dr. Rush shows the advantage of opium, and goes on to say, "I think I have seen the happiest effects from that excellent medicine in such cases, in destroying useless pains and shortening the progress of the labor. How far a medicine (if such can be found) so powerful as wholly to suspend the sensibilities of the nerves, without impairing their irritability, might succeed in destroying pain altogether, I know not."<sup>4</sup>

In this letter, aside from the special point that I make in the present paper, Dr. Rush demonstrates, throughout, that he was a skilful obstet-

<sup>1</sup> The biography of this gentleman will be found in our Permanent Secretary, William B. Atkinson's work, "The Physicians and Surgeons of the United States." Philadelphia, 1878, p. 44.

<sup>4</sup> Medical Repository, vi, 1803, p. 24.

rician. In its very title, he closely associates the pains of labor with its dangers, he announces that they can both be lessened, he recognizes that they are the potent cause of subsequent disease, and he teaches its prevention. Here, as in the passage quoted by Dr. Faget, Dr. Rush foreshadows the great discovery which has taken from parturition its anguish, without interfering with its progressive natural action, and has greatly lessened its perils to mother and child.

Upon referring to the work of Walter Channing, of Boston—a native, by the way, of Newport, and upon this occasion to be spoken of with especial honor—to whom, as also to Sir James Y. Simpson, as the first physician to induce artificial anæsthesia in childbirth, Dr. Faget gives due credit, I find this comment: "It is grateful to recur to the opinions of our distinguished countryman (Dr. Rush) on a point which he approached with sentiments of the profoundest reverence, on account of the authority on which it is supposed to rest, whilst he successfully controverted the popular inference, namely: the penal character, involving a physical necessity of pain in labor." He had conceived "a hope. Was it not prophecy? Had it not so much of truth as a basis, that the great discovery of our own day seems to be the revelation of that truth? His doctrines were rather inductions, or the generalizations of facts, than theories." He "expresses 'a hope' of the discovery of a remedy of (obstetric) pain," but he also states "the reasonableness, the moral evidence, of that hope, so that it becomes faith."<sup>5</sup>

It will be noticed that Rush distinctly contemplated the removal of sensibility alone, and the retention of uterine activity. His views therefore were precisely those of the best authorities of the present day, regarding the conduct of natural labor. He was in general sympathy with Sydenham, whose works he edited, and for whom he even named his country seat, and it is not unlikely that through studying upon this account the more closely the effects in labor of opium, his opinion of which I have already quoted—and that preparation of it which is known as Sydenham's to the present day—he came to perceive the end that was to be searched for in childbirth beyond merely soothing its pain, namely: the preservation unimpaired of uterine contractility and expulsive power. Dr. Rush, besides, was far in advance of his time in recognizing the evil effects of alcohol upon the human system, both in health and disease. One of the cases which he reports was of painless labor "during a fit of drunkenness." This would have added to his desire to produce the effect, temporary anodynia, while avoiding its disreputable and injurious cause.<sup>6</sup>

That Rush had anticipated by nearly fifty years

the magnificent idea which was to result in freeing woman from the burden of incalculable suffering that had been borne by her through the ages, seems to have been recognized by no one besides Channing, save Faget and one single other.

In 1876 Dr. Gaillard Thomas both noticed and quoted Rush's aspiration, yet he seems to have mentioned it as but an incident in the course of his generous tribute to Simpson, the more striking from appearing in the very same book wherein was made the direct implication, of course an accidental one, that the anæsthetic property of chloroform was an English and not a Scotch discovery.<sup>7</sup> Dr. Thomas, in speaking of the introduction of anæsthesia into the lying-in chamber as an era in the history of obstetrics, thus declares: "It is somewhat singular that after the discovery of anæsthesia in this country, after the prediction, long before its discovery, by one of America's greatest physicians, that 'a medicine would be discovered that should suspend sensibility altogether, and leave irritability, or the power of motion, unimpaired, and thereby destroy labor pains altogether'; after it had been employed here in hundreds of cases for surgical operations, this link of the chain should have been forged by a European. Yet such was the case, and far be it from any American to begrudge him one atom of the glory which he deserves, or to endeavor to dim its lustre by 'faint praise.'"

We do not find Rush's prophecy, where of all places it would have most naturally been looked for, in the bitter letters of the elder Bigelow, of Boston, in 1869 and 1870, to Sir James Simpson, nor in the minute statement, six years later, by his son,<sup>8</sup> although both of these gentlemen were colleagues of Channing in the Medical School of Harvard University.

Channing seems to have been the first to discover the great suggestion made by Rush. His reference to it in 1848 was apparently perceived by none till Thomas in 1876—thence by none till Faget in 1880, who again was unaware of the allusion to it that Thomas had made. From 1880 till now there exists the same utter silence as before.

I make this statement with hesitation, for the fact seems almost incredible. Several friends, however, have assisted me during the present investigation. From the Treasurer of the Rush Monument Association, and ex-President of our own, Dr. J. M. Toner, the person of all now living probably most familiar with the life of this signer of the Declaration of Independence, I have received for examination many biographies of Rush,<sup>10</sup> from his own very extensive collection of

<sup>5</sup> "A Century of American Medicine, 1770-1870," Phila., 1871, p. 150.

<sup>6</sup> *Ibid.*, p. 262.

<sup>6</sup> "An Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind," 1785.

medical works now in the Congressional Library, and he has besides aided me in the search itself. Dr. Toner writes me as follows: "I have nowhere found allusion to the wonderful hope expressed by Dr. Rush." Dr. Paul F. Mundé, of New York, who as editor for so many years of the *American Journal of Obstetrics*, aside from his own special researches in this direction, has had reason to keep informed of all that has been published upon midwifery, reports a similar result. "I do not recollect," he says, "ever seeing the name of Dr. Rush in this connection. Certainly, he had a remarkable gift of prophecy!" Dr. James R. Chadwick, of Boston, the founder of the great medical library at Boston and a most faithful observer of all that occurs in obstetrics, writes me to the same effect. "The prophecy of Dr. Rush was new to me. I have not seen it alluded to by any writer. It is of very great interest." And Dr. Gaillard Thomas, whom alone besides Channing and Faget I had found alluding to Rush in this connection, informs me that he recollects no one who has appreciated Rush's prophecy save Channing.

You and I would, I think, have felt aggrieved had it been intimated that we were unfamiliar with the works of Rush and of Channing, and the chapter by Thomas, but for myself I am willing to acknowledge that having eyes I saw not, neither did I understand. With all my interest in the general subject, the full significance of Rush's true position toward this question, has not struck me until now.<sup>11</sup> A student at Harvard University during the first use of sulphuric ether at the Massachusetts General Hospital, and though still an undergraduate a witness of many of the earlier operations during which ether was there employed—a friend of Dr. Charles T. Jackson, whose gold medal from the Swedish Government commemorates that, however he would have neglected of himself to communicate the discovery to the world, the idea of employing sulphuric ether

as an anæsthetic was due to him—a pupil of Channing, and of Simpson, whose great Montyon gold medal from the Institute of France was given not merely for his other transcendent merits, but because by annulling the pains of childbirth, he thereby removed the primal curse, and lessened in almost equal degree both infantile and foetal mortality, and by employing chloroform as the agent, was better able than with ether to momentarily suspend sensibility, in Rush's language, without impairing uterine irritability—and having myself twenty-six years ago, in 1863, contributed by an essay upon the subject<sup>12</sup> that Thomas in the "Century of American Medicine," already referred to, was kind enough to call "of considerable value,"<sup>13</sup> to the work these preëminent philanthropists had commenced in reference to the general employment, even in natural labor, of artificially induced anæsthesia, I have yet failed, till the present moment, to properly recognize Rush in one of the most beneficent of the many labors in which he was engaged. His work as a sanitarian had been duly appreciated.<sup>14</sup> He had published papers upon diet,<sup>15</sup> climate,<sup>16</sup> military hygiene,<sup>17</sup> leprosy,<sup>18</sup> hydrophobia,<sup>19</sup> and yellow fever,<sup>20</sup> and for his great services during the epidemic of the latter in 1793, he had received unusual honors; among them, gold medals from the King of Prussia in 1805 and the Queen of Etruria in 1807, and a diamond ring from the Czar of Russia in 1811. The chief point upon which, I predict, his lasting fame will rest was, however, wholly unappreciated during his life, and now, seventy-five years after his decease, it seems to have escaped the notice of all his biographers and to have been but three times alluded to by writers upon midwifery.

Very interesting, moreover, appears the fact, to which Dr. Faget has also drawn attention, that Dr. Rush studied at the University of Edinburgh,

of Independence—Rush." Philadelphia, 1823, Vol. iv, pp. 249-288.

and had access to that wealth of mediæval medical literature in its library in which Simpson so revelled, and whence he was accustomed during his researches into obstetric medicine, surgery and sanitation, to adduce so many wholly forgotten precedents. As a student myself of that ancient school, I can appreciate the influences that formed Rush's character, as observer, medical philosopher and practitioner. Born near Philadelphia in 1745, Dr. Rush took his degree at Edinburgh after two years of study there in 1763, and he proved Scotch in his subsequent methods of thought and of action, till his death in 1813.

Channing again was a pupil of Rush, to whom it was always his delight to affectionately refer. He graduated as a physician at the University of Pennsylvania in 1809. Through Rush's influence it was, undoubtedly, that he in turn resorted to the University of Edinburgh, and there drank from the fountain that had inspired his preceptor. It was not till 1812 that he received his medical degree at Harvard. He retained through his life his affection for the Scotch capital. His relations with Simpson were intimate, and it was his delight that while Simpson was the originator of actually induced anæsthesia in midwifery, he himself was the first American to urge its general use for this end. So far as the realization and final employment of obstetrical anæsthesia are concerned, Edinburgh, through Channing its American, as well as Simpson its direct representative, well earned its palm. It is strange that the first conception of the idea should also have been by a foster child of Edinburgh, Dr. Rush. Again, Drs. Channing and Charles T. Jackson were friends and close neighbors. They had long before occupied the relations of teacher and pupil. They lived upon the same street, their houses being but a few feet apart. They were upon confidential terms of acquaintance, with similar tastes for abstruse research in very unusual directions. The only wonder now is that the one, knowing the need of suffering woman which Rush at the very commencement of his medical studies had taught him, for an artificial solace at the time of her greatest physical trouble, and the other, having discovered and bearing for so long in his mind the anæsthetic qualities of the agent which gave the first step towards the solution of the problem—that these men should not have come more closely together, and the obstetric world's great secret been earlier made known. Jackson was an accomplished chemist, and searcher for recondite applications of his science to art, and Channing a most remarkable medical antiquarian. With Channing as his coadjutor, Jackson would not probably have been so grasping for riches and for fame as he proved when associated with Morton, though this may have been but the premonition of the mental malady which, as in the sad case of his competitor,

Horace Wells, occasioned his death—while poor Morton, jealous and all tenacious to the last, died, though more suddenly than Jackson, just as consequentially. The fearful quarrel, that involved in its scandal wellnigh the whole profession of the time, and indeed almost the good name of science itself, would perhaps thus have been avoided, and the birth of the divine idea might not have been, as it was, attended by the sundering of intimate personal ties, by deep distress and by wailing, the echoes of which have as yet scarcely ceased.

There is a strong parallel that may be drawn between the posthumous estimates of the two illustrious physicians of whom I have chiefly spoken in the present communication. It was at the close of the meeting of the American Medical Association at Washington, in May, 1870, that the news was received of Simpson's death, telegraphed by his son to your present reader within a very few moments after the event had occurred, and there are undoubtedly those now here who recollect with what regret the announcement was received by the Association, and the solemnity of the memorial meeting which was held immediately afterwards by its delegates and the medical residents of Washington. Whatever the previous feeling of individual members of the profession, in favor of ether or of chloroform as an anæsthetic, or regarding the respective claims of Boston and Edinburgh, which had improperly been made to seem antagonistic, all cavil was silenced at the touch of death. It has been so also with Dr. Rush. The rivalries of his time, which were intense, are forgotten. His own city, to which in his lifetime he was no prophet, points to him with pride. The great professional centres of our continent vie with each other in recognizing him as the most fitting representative of early American medicine, and the chief ornament of the far reaching University whose distinguished provost is one of the orators at the present meeting of the Association. Seventy-six years have now passed since the death of Rush. It is but of late, as our lamented ex-President Gross said of our equally great McDowell, that "the chaplet that should have been worn on his brow has been placed by a grateful profession upon his tomb."<sup>21</sup> To add a fresh leaf thereto is not my privilege merely, but a filial duty. It is seldom that a man can trace back for a hundred years the influences that have shaped his own life and the little work he may have attempted to accomplish for medicine. Rush was at Edinburgh in 1768. It was entirely through his advice that thither went his pupil Channing. It was by Channing's influence that it became my own Mecca in 1854. Sincerely grateful, therefore, I am to Rush, and delighted to aid towards the high esteem in which he will henceforth be held by our obstetrical brotherhood. Should the question ever arise, from the sequences

that I have endeavored to trace, whether Simpson, like Channing, had appreciated Rush's prophecy, I am sure from what I know of his character, that such could not have been the case. He ever freely gave of his knowledge to the world, concealing nothing, and he was particularly generous in his treatment of Americans, whether living or dead. Even after Channing had quoted Rush, the full meaning of the American prophecy seems to have escaped Simpson, as it has us all, else he would have been sure to have used it, sharply, when replying to the senior Bigelow, equally unaware of its existence. The latter of Simpson's answers to the Boston sage was written, it will be remembered, from his deathbed. It was his farewell to the profession, of obstetrics and at large—happy, he said, "if it tend to fix my name and memory in their love and esteem."<sup>22</sup> At such a solemn hour, had he clearly understood what we now know of Rush, his would have been the hand, promptest of all, to give justice where it was due.

Just as John Bell, of Edinburgh, in 1794 urged the performance of ovariotomy, and in 1809 it was successfully accomplished by his pupil, Ephraim McDowell, of Kentucky, so in 1802 or thereabouts Dr. Rush, a graduate of Edinburgh, foresaw the possibility and need of obstetrical anodynia, and in 1847 his dream, by all forgotten, became reality at the hands of the Edinburgh professor, Dr. Simpson.

Dr. J. R. Chadwick has asked me if Rush could have been familiar with Joseph Priestley's laboratory experiments with nitrous oxide. I have no doubt that such was the case, aside from the fact that after 1794 Priestley was a neighbor of his in Pennsylvania, and most probably also a personal friend. (It is another curious coincidence that a near relative of the philosopher, Dr. William O. Priestly, of London, should have been one of Simpson's best loved and subsequently most distinguished pupils.) It is moreover possible that Rush had noticed what Davy had just then suggested, in 1800, regarding the use of nitrous oxide as a purely *surgical* anæsthetic. However this may be, the fact remains that Rush had advanced far beyond the point assumed by Davy. What he desired and foretold was not the destruction of sensibility alone, but the retention with this, in full activity, of a certain usually dormant, but in obstetrics all-important, system of nerves. Davy made no reference to allaying the pains of childbirth. His whole thought was of *surgical* anodynia, the mere quieting of general sensibility. He evidently never dreamed of obstetrical anodynia, where nervous irritability and uterine contractility must be retained unimpaired. And so with Boston. To Boston, indisputably, belongs the honor of having first demonstrated the general practicability and safety of induced surgical anæsthesia,

against which there did not exist the then seemingly grave theological objections that were so vehemently urged against its *obstetrical* employment, and which made the triumph in this direction the more difficult, and yet for this very reason the more to be commemorated.

#### THE RUSH MEDALS.

I have thus briefly presented Dr. Rush's claim to be honored by you, gentlemen, the teachers, cultivators, and practitioners of midwifery in the United States. Eventually, the memorial determined upon by this Association, in collecting the funds for which Medical Director Gihon, U. S. N., Dr. Geo. H. Rohé of Baltimore, ex-President Toner of Washington, and others of your Committee, have labored so faithfully, will be erected, and mankind will be reminded of "the Sydenham of America."<sup>23</sup> It remains for you to influence the profession toward the hastening of that time, marking at last "the Rush renaissance."<sup>24</sup> Meanwhile, that you may contemplate the features of the man himself, and appreciate the better the parallel that has been drawn between him and the great light of British medicine, I show you reproductions, from my own collection, of the two medals that have been struck in his honor at the U. S. Mint, of which he was long the Treasurer. They have been photographed for me from the originals, greatly enlarged, by my friend, Mr. Clarence Stanhope, of Newport, and I wish that copies could be placed in every medical, historical and public library in the country. The following are their descriptions:

1. Obverse. Bust, with queue, to left; a neck cloth under the collar. Beneath shoulder, F(ürst). Inscription: BENJAMIN RUSH, M.D., OF PHILADELPHIA.<sup>25</sup>
- Reverse. A river, flowing from side to side forwards; in background, the setting sun, with clouds and mountains. Large trees in foreground, to right; to the left, SYDENHAM. In front, a block of stone, on which: READ—THINK—OBSERVE. Upon this, an open book. Beneath, to right: M(ozitz). FÜRST FEC. Exergue: ANNO. MDCCCVIII.

Silver (?), bronze, lead. 41 mm. 27.

The legend upon the reverse is from the close of his lecture, "On the Causes which have Retarded the Progress of Medicine." It is very similar to the "HEAR. READ. MARK. LEARN." upon an old medal of Christ's Hospital School, London, which is in my collection, in silver.

I have this medal of Dr. Rush both in bronze and lead. It is also at the Surgeon-General's Office at Washington, from the Lee Collection, in the former of these metals. It is very rare, and seems unknown to all numismatic writers. The die cutter, Fürst, was at the time an assistant engraver at the U. S. Mint.

<sup>22</sup> "Modern History of Anæsthesia" (Anæsthesia, Hospitalism, etc. Edited by Sir W. G. Simpson, Bart.) Edinburgh, 1871, p. 41.

<sup>23</sup> The above term was first applied to Rush by his friend and biographer, Dr. Lettsom, of London. Loc. cit., London, 1815, pp. 3, 15.

<sup>24</sup> C. K. Mills. "Benjamin Rush and American Psychiatry," Medico-Legal Journal, December, 1886; Reprint, p. 2.

2. Obverse as in preceding.  
Reverse. An altar, upon which rests an open book. In front, upon an oval panel, a bust of Æsculapius, with serpent-encircled staff. In another panel, at right, an urn. Beneath, to right: M. Furst Fec. Exergue: A(nno). MDCCCVIII.

Bronze, gilt bronze. 41 mm. 27.

Unknown to all writers upon medals. Still rarer than the preceding. It is in the Lee Collection and my own.

I have endeavored, but thus far in vain, to ascertain the history of these medals, and have been aided in my inquiries by Dr. Wm. Pepper, of Philadelphia, through whom I have received letters from Hon. A. Loudon Snowden, long Superintendent of the U. S. Mint, and Mr. R. A. McClure, in charge of the Mint Cabinet. Col. Snowden has written, under date of March 21, 1889: "The Dr. Rush medal is not in the Mint Cabinet, and its history is obscure," and again upon the 27th, "I have taken considerable trouble to seek information from several sources, but thus far without any particular success," Mr. McClure, like Col. Snowden, was aware of the existence of but the first of the medals described above, and this he had seen at Mr. Alexander Biddle's. He reports: "Mr. Biddle did not succeed in finding any information or clue to the occasion of the striking of the Rush medal. I went to the Ridgway and Philadelphia Libraries, and the rooms of the Historical and Philosophical Societies, and looked over the file of two daily papers of 1808, the year in which the medal was struck, and found nothing." Messrs. Bailey, Banks & Biddle, prominent medallic artists of Philadelphia, have also been unable to furnish me with the slightest information. From this will be perceived the extreme rarity of the medals, and the fact that though both of them were struck at the Mint, the very existence of one of the two had passed from the knowledge of the Mint authorities. Of the first of them, there are said to be known two specimens in silver. It was remarked several years ago,<sup>25</sup> before the revival of an interest in medical numismatics, that these would be cheap at \$20 each. They would probably now bring very much more than this sum, and it is to be hoped that they have been secured for permanent preservation by medical institutions, though as to this I am as yet uncertain.

The portrait bust of Dr. Rush upon the medals was undoubtedly from sittings for the purpose, since they were executed five years before his death. It will therefore be of service, in connection with the familiar painting by Sully, in giving his exact features for the monument undertaken by the Association, when at last its construction shall be commenced.

In conclusion, a brief quotation from the "Elegiac Poem on the Death of Dr. Rush," may not seem out of place:

"Unchecked by ridicule, unawed by rules,  
Fallacious dogmas, and the pride of schools;  
With all the ardor of aspiring youth,  
From fair experiment, the test of truth,  
Deep searching Rush ingenious reasonings drew,  
Bold to defend, and potent to subdue!  
Determined truth by every mean to try,  
Where others dared not gaze, 'twas his to fly;  
He rescued truth from mad opinion's maze,  
And caught from Science her inspiring rays;  
Beamed o'er the healing art a radiant light,  
Like orient phosphor o'er the mists of night."<sup>26</sup>

How appropriate beyond the intention of its writer, who was but lamenting his decease, is the following, to Rush's supreme anticipation of the discovery and application of artificially induced anaesthesia to midwifery!

"Thy light, bright Science, to this sphere confined,  
Was far too little for his mighty mind!  
Which soared beyond this world, and broke away  
From darkened nature to a world of day."<sup>27</sup>

(The above paper was read before the Section of Obstetrics and the Diseases of Women, and by vote of the Section was referred to the Association itself, with the recommendation that it be read in general session also, as containing matter of interest to all practitioners of medicine.)

## MODERN SANITARY CONDITIONS.

*Read, by invitation, before the Section of State Medicine at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY GEORGE E. WARING, JR.,  
OF NEWPORT, R. I.

Early in 1855, moved by the most distressing condition of the sick and wounded in the hospitals of the Crimean army, Lord Panmure commissioned Dr. Sutherland, Dr. Gavin and Mr. Rawlinson to proceed to the Bosphorus and to the Crimea, and to take instant measures for the improvement of the sanitary state of those sadly crowded buildings.

Mr. Rawlinson, a man of sound sense, great practical skill, and a genius for direct and positive action, and then in the prime of life, was quick to apply to the appalling conditions with which he was confronted those well-trained abilities which had already marked him, and which still mark him, as one of the great lights of Sanitary Engineering.

The order was issued on the 19th of February. In less than three weeks the work at Scutari was already progressing and within a month a marked effect was obvious.

Kinglake says: "Then came on a change which, if only it had been preceded by mummery instead of ventilation and drainage and pure water supply, would have easily passed for a miracle. Down went the rate of mortality. Having already gone down from the terrible February rate of 42 per cent. to 31, it descended in the next fortnight to 14; in the next twenty days to 10;

<sup>25</sup> American Journal of Numismatics, 1885, p. 79.

<sup>26</sup> Loc. cit., Philadelphia, 1813, p. 15.

<sup>27</sup> Ibid., p. 31.

in the next to 5; in the next to 4; and finally, in the next twenty days, ending on the 30th of June, 1855, to scarcely more than 2."<sup>1</sup>

This result was achieved by physical changes effected by intelligent engineering.

Dr. Billings, in his work for the Tenth Census of the United States, estimates the death-rate of the whole country at about 18 per 1000. It cannot be questioned that a proper regulation of the universal conditions of human life throughout the whole country would reduce this rate to 12 per 1000; saving every year, on the basis of the present population, not fewer than 365,000 lives which are now sacrificed to neglected filth, with its attendant contamination of the soil on which we live, of the air we breathe, of the food we eat, and of the water we drink.

Disregarding for the moment the enormous loss of power and loss of heart, and the manifold suffering incident to the sickness these deaths imply, we are confronted with the stupendous and disgraceful fact that in these prosperous and intelligent United States, of which we boast as the home of the highest modern civilization, one thousand human beings are stricken to death every day, cruelly, needlessly, wickedly—solely because of the lack of that which it needs only intelligent direction to secure. We thus wantonly destroy every three years more lives than were sacrificed, directly and indirectly, by both North and South during the War of the Rebellion. The sum now paid for pensions during three years, if intelligently administered, would cover the improvements required to prevent these deaths.

The epidemic of yellow fever in 1878 aroused the active sympathies of the Nation, and even frightened Congress into an unwonted momentary activity in behalf of the life and health of the people. The deaths from that epidemic did not amount to more than 18,000. The lives wantonly sacrificed to preventable disease amount to that number every eighteen days.

The whole country now stands aghast at the fearful sacrifice of life caused by the bursting of the dam above Johnstown. Estimates of the actual loss are necessarily vague, but it is entirely safe to say that thrice each month, thirty-six times each year, as many persons die lingering and painful deaths, caused by a universal neglect on the part of the whole people that is no less culpable than was the neglect of those charged with the construction and care of the disastrous dam.

We stand, one and all, we and our wives and children, subject to an ever-present and entirely avoidable danger of a sort that every man, woman and child in every enlightened country has a just right to be protected against.

Such protection it is quite within the power of the people themselves to secure, but the people themselves must secure it. All that we can do is to point out the way and to emphasize the necessity. The huge task is one whose doing can be compassed only by the force of an aroused public opinion; our task, hardly less huge, it must be to awaken and vivify that opinion.

What is to be done relates chiefly to the complete removal of the organic wastes of life before the beginning of putrefaction, and the ultimate disposal of these wastes, by methods now understood, in such a way as to reduce them to their elements without such contamination of earth, water or air as now reacts so fatally on the population. The process would be simple. Its seriousness arises only from the wide and universal dissemination of points needing attention, and from the enormous aggregate of cases to be treated. The adequate sanitary improvement would involve drainage and garbage removal, water supply, and some improvement of ventilation. By drainage, we mean, in this connection, the removal of filth in sufficient currents of water, and this is by far the most important thing to be done. Accumulations of filth not susceptible of removal in water must be removed in other ways or destroyed. While it is obviously necessary to bring water from a distance for the supply of those who live in large towns, village communities may safely rely on well-water, if only the water of the ground be protected against contamination, as it would be by the complete removal and proper disposal of organic wastes. So also, with the prevention of putrefaction in and about habitations, the need for costly artificial ventilation will be greatly reduced. The freedom with which air passes not only through the imperfections of our buildings, but through the very walls of our houses, is shown to suffice for the favoring of health and longevity, by the great number of aged and robust persons habitually living in an atmosphere that would seem intolerable to one accustomed to better conditions. It is not to be understood that the most complete ventilation is not desirable, only that if all waste matters be properly removed and disposed of, and if the water supply be made pure, a reduction of the death-rate to 12 per 1000 might fairly be expected, even without such ventilation as any sanitarian would think desirable.

The foregoing announcement is based on no untried theory. We know by experience that under wholesome conditions of life a general death-rate of 12 to 1000 can be reached in towns, and that a lower rate is possible in the country. We know that where organic refuse, including that which is voided from our persons, is completely removed without the possibility of fouling the surface or the interior spaces of the soil, without the possibility of contaminating our supplies

<sup>1</sup> The exact figures are 42 7/8, 31 5/8, 14 4/10, 7 5/8, 2 4/3, 2 2/3. The average rate in military hospitals in England was 2 2/3.

of water and food, and without the possibility of sending the gaseous products of its putrefaction into the atmosphere that we breathe, the conditions requisite for the maintenance of the zymotic diseases are substantially annihilated, and a great cause of *malaise*, debility and suffering is averted. If the improvement includes, as it often will in an incidental way, the correction of hygrometric conditions tending to the production of malaria, the relief will be greatly magnified.

It may, therefore, safely be asserted, in the light of what we know of improvements that have been effected by simple changes of physical conditions, that a proper application of the sanitary arts of the engineer would of itself suffice to save to us the thousand daily lives now thrown away, and to multiply greatly the happiness and efficiency of myriads whose sickness, though not mortal, is grievously painful and incapacitating.

It is, of course, not to be understood that even the zymotic diseases, which are chiefly referred to in this paper, are to be withdrawn from the domain of the physician and entrusted to the unaided efforts of the engineer. The great advance in sanitary achievement in the past fifteen years has taken place not in the field, but in the laboratory; it is in your profession, not in ours, that the great wonders have been wrought.

It has long been considered that the rough measures of the drain builder and the water purveyor were effective in warding off much disease and death, but the knowledge under which our results have been achieved has been very largely of an empirical character. It was only when the biologist entered the arena that real knowledge of the subject began, and although the biologist is yet only at the portals of the vast temple of knowledge to which he has so lately found the key, he has gone far enough to indicate quite clearly the reasons for the success of sanitary engineering, and even to justify a conviction that he has, dimly perhaps, but surely, indicated a new way of escape from much of our existing physical suffering and death.

How many of our diseases are caused by the invasion of specific organisms we are far from knowing. We do know that some of them are so caused, and the study of the life history of pathogenic microbes has already indicated more than a possibility, not only that their invasion may be prevented by suitable measures, but also that after the invasion of our bodies they may be, by measures yet to be defined, rendered powerless to perform their appointed work of injury or destruction. It would indeed almost seem that the elixir, not perhaps of life but of health, will yet be shown to lie in the death potion of the microscopic invaders of our blood and tissues. Until this is definitely shown, and probably still more after it has been shown, your profession and ours must

work hand in hand to stay the tide of destruction by which the community is not only menaced, but to which it is actually subject, and from which it is constantly suffering.

You need not now be detained for a discussion of the processes by which the great end in view may be accomplished. These are tolerably well known and are to become better known day by day. What is necessary is that you and not only you, but all of your professional brethren, and not only they, but all who are subject to their professional ministration and to their influence shall be made to know and to feel that this great calamity is upon us and has been upon us in constantly decreasing degree for all time, and that it lies within our power to hasten its decrease in the future until the conditions of life of this whole people shall have been made what they might be and should be.

The whole purpose of this paper is to impress upon you the commanding need for action—an action that shall bring modern sanitary conditions into conformity with modern civilization.

---

## THE INFLUENCE OF MEDICAL JOURNALS ON THE MARCH OF SCIENCE.

*Read before the American Medical Editors' Association at Newport.*

BY T. D. CROTHERS, M.D.,

OF HARTFORD, CONN.

In January, 1889, there were published in this country and Canada, 142 journals which claimed to represent the science and art of medicine.

The influence these journals have on the march of medical science opens up a field of unusual interest.

The profession are every year depending more and more on medical journals for contemporaneous history, criticism, and guidance, and every year these journals are giving more accurate records of the movements of science, of the rise and fall of theories, of the evolutions and revolutions that follow along the line of medical scientific discovery.

The time has come when accurate conceptions and misconceptions of truth must seek a hearing through the press. Books are too slow, pamphlets are not read, the medical journals must present and defend the facts and theories continuously and persistently. Any theory supported in books alone has little chance of attracting attention. No matter how absurd the theory may be, if it has an organ in the press, it will be heard. Hence, to-day, in the list of 142 journals we can trace a history of the empiric stage of science; we can see the superstition and credulity and the quackery which gathers about the birth of all truth; we can see the psychological growth and conflict of truth and error, and realize that all these journals of all degrees and kinds are un-

consciously writing the history of the world's progress. We who are journalists, each hope that our work approximates to that ideal of absolute truth that we are striving after, above the levels of transient medical journalism, and along the very front lines of progress. The reality of our progress is in some degree realized by the constant appearance in the medical press of the latest discoveries and truths of medicine, and we feel that in some measure the march of science takes its shape and direction from our efforts. We who are the actors on this stage cannot fully realize our individual influence in the play, nor can we judge from the applause of the audience. We are too near each other, and our mental vision is too limited; but we can discern the imperfections of our work, and prompt each other from the wings. When some of our enthusiastic brothers find themselves overwhelmed with confusion by the discovery of having advocated some absurd theory, or defended some new remedy which proves to be inferior to cold water, we can cover his exit with silence and charity. But when some of our brothers are attacked with dogmatism and have delusions that they are the central orbs of all science, or that other strange fatal disease, and its opposite, icy conservatism and frothy freshness, we put on garments of mourning long before life is extinct.

Bowing on the stage, or lounging in the wings, gives us some clear views of human nature and science. The search for truth and the effort to present it, brings out all the stars, the tragedians, the comedians, the supporters, and the army of figure heads.

As evolutionary optimists, we can catch glimpses of a progressive movement ever onward, although in our work this march of science seems like a confused advance and retrograde alternately. The incessant revolutions of theories and practices casts a shadow over our dogmatism and boasted exact experience, making it clear that the great drama of which we are actors and historians is beyond our present comprehension. The influence of medical journalism on the march of science, is also beyond our present comprehension. We can only draw some outline facts and apparent conclusions of this influence from a general study of the journals which claim to represent the science of medicine to-day. Of the 142 journals which began the year, death has claimed a certain number, but recruits have promptly filled their places, and it is safe to say that there are no vacancies. But the long felt want is still urged. Journals come, and journals go, and the procession goes on.

Among the real scientific journals three distinct classes appear: The *general*, the *special*, and the *encyclopedic* journals.

The *general journals* aim to represent the entire field of medicine, to give papers and discus-

sions covering every line of medical research. The claim of being practical and addressing themselves solely to the busy physician is often contradicted by the work. Such journals like the single volume text-books fail, because the subject has outgrown the limits they would place upon them. A single volume text-book on practice or surgery can only be an outline view, more or less imperfect. So a general journal which attempts to spread the entire field of medicine before its readers, must do so in outline, and fail in many respects. The journals of to-day cannot do what was possible a quarter of a century ago. The heavy quarterlies are fast disappearing, and even the monthly is losing ground. Our journals must come weekly, and not far away the medical dailies will appear.

The journals that are taken by the general profession to-day must come often, and bring theory and practical experience; they must in newspaper parlance "boil down" every thing, and discriminate between the facts and fancies of authors. The general journal of to-day fails when its pages are loaded down with minute descriptions of disease and the exact action of remedies on the organism. It fails when the editorials are acrimonious and dogmatic. It fails when it dwindles into a newspaper of personal items and gossip, and apes the secular papers in tone and character. It fails when it assumes that medical science has advanced to the frontiers of positive truth in any direction. When the ideal general journal comes for the mass of physicians, it will be a weekly and daily.

It will be strictly impersonal and reflect the conclusions and results of scientific study up to the present.

It will avoid the ranks of dogmatism and credulity, and follow a line of frank conservatism towards all science. It will aim to find not the practical alone, but the literal roads for the discovery of the probable facts and laws of science.

The ideal journal will arouse and stimulate further inquiry, and the reader will never be satisfied with the conclusions which it presents. The ideal journal will be an outline of what appear to be the best sustained facts concerning the problems of medicine. Such a journal must have concentrated power and force of editorial talent, to write the history of the medical advances truthfully and clearly to-day. Such work helps on the march of science and is growing more and more essential.

The *journals devoted to special fields* of medicine occupy a different position.

They give the observations of the picket-guards of science, the impression of men who follow up a special line of research. They make the first surveys of new countries, which of course are imperfect and lacking in many details.

The probable facts and their conclusions are

only tentative, and are given for the purpose of exciting inquiry and examination.

The specialists' journals are mapping out the topography of new countries, and making observations of its flora and fauna, which must be corrected by the armies of the rear, and more than all other journals do they influence the growth of science, and are in turn influenced by it. The multiplication of specialists' journals comes from the rapid widening of the fields of medical study; it shows clearly that the day for the general journal is drawing to a close; that like the single volume text-books, the science of medicine can no more be concentrated in one journal. In the twenty or more special journals that occupy the field in this country, this fact is more and more obvious.

From the smallest and most imperfect beginnings they are slowly and surely coming to "the front," and in the twentieth century the science of medicine will be studied in these journals. The specialist journals of to-day, with all their weakness and narrowness of work, are nearer and more influential in the real progress of science. They push on the exploration, from the mountain tops into the valleys, and along the river bottoms and plains of science. They map out the field for minute and exhaustive study, and give the results of individual work as no other journal can. Such journals cannot exist alone commercial standards of value; they come in obedience to demands of a special audience; their readers are contemporaries, workers along the same lines of research. They can only live where science is most aggressive, most active and most advanced. The general journal is of the past, the special journal is of the future. The one is a survival, the other is an evolution. The great text-books on the different branches of medicine are more and more the outgrowth of the work of special journals, the condensation and elaboration of views that have appeared first in such journals. On the growth and development of special journals, many of the great problems of medical science will depend.

The last class of journals that are prominent are the cyclopædial journals. They essay to give condensed summaries of the progress in all departments of medicine. Many general journals combine this feature with their work.

The ideal journal, or book, that will give a fair view of the medical progress of to-day is yet to come.

The attempts in this field are more promising than real. The readers of this class of literature and journals are filled with conflicting emotions concerning the near approach of a medical millennium, and the disappearance of the good old facts of our fathers and the humiliating thought that all truth comes from over the sea. No true science in this American *Nazareth*. The

ideal journal to occupy this field will be a great power in the evolutionary march. The ideal book giving a correct view of the progress is far beyond the journal or the special department in the journals.

These three distinct classes of journals appear either single or combined in all the medical papers that claim to represent the science.

*Medical journals* are slowly emerging from the stage of childhood, in which the personal views of its managers are more prominent and emphatic than facts of science; a stage in which the intense personality of certain men and colleges, or teachers, are fixed points about which all other truth must revolve. Every advance is judged from this point of view. Such journals resolve the science and art of medicine into fixed laws, that never change. They stand out in the great march as obstructive, like the Bourbon family, they never learn anything and never forget anything.

The *mutual admiration period* is another phase of the childhood of journalism. Journals of this class are passing away, and are very interesting psychological studies. The personal news items, and comments stage is another sign of youth in journalism. Sneering doubts, and fulsome endorsement of every new view of science are equally unscientific. We might go on and tabulate a long list of signs of youth and feebleness in the medical press, but a little higher view will show us that this is part of the natural history of the sudden birth of a small army of medical journals, who are each struggling to represent the whole or some part of this great ever-widening land of science.

Medical journals, like the science which it represents, are growths or evolutions from the lower to the higher, or devolutions from the lower still farther back. Medical advance is thoroughly revolutionary, and our best facts to-day disappear to-morrow, and give place to newer, wider views. Our journals ought to be histories of this restless change. Histories above all personal interest or motives, except to give the most probable facts and conclusions, sustained by all the evidence at our command.

As medical journalists we can never represent or influence science by allowing personal dogmatism or personal gossip criticism to appear in our work. We can never represent or influence science by endorsing an assumption that any one range of facts comprise the whole truth, or that the last and final truth is bound up in any theory. We can never represent or influence science by a partisan support or defence of any minute statement of disease or its exact laws, or the action of drugs on the system, or theories of physiology and psychology. *Medical journalism* to represent and influence science *must assume* the position of a judge, hear all the evidence, and then present

to its readers those facts which seem best supported by research, theory and experience. Medical journalism to represent and influence science *must discriminate between* the probable and the improbable, between the statements and theories of men, who trust to fancy or to inductive reasoning, must discriminate between facts that are apparent or assumed, and insist that the record of sciences to-day have some support from the facts of yesterday. If this cannot be, the record must have an assemblage of probable evidence, that shall give it position and recognition.

*Medical journalism to represent and influence science* can never be a newspaper or a transient journal of the hour. It must rise to the level of the great laws which govern the evolution and dissolution of humanity. The individuality of the discoverer is as nothing compared with his discoveries. The truths of science require a higher standard of representation than the follies and accidents of life. While the 142 journals in this country that claim to represent medicine are in many instances sad reflections of so-called science, yet the American medical press as a whole is full of hopeful promise. While the quarterlies are doomed, and the monthlies are becoming more and more uncertain, the weeklies are growing in freshness and vigor. A new era is dawning for journalism. Both authors and editors must give the readers the clearest, briefest facts and evidence to sustain them. The theories and opinions of the fathers in medicine have of themselves no longer any weight, unless they have a direct bearing on the present. Papers loaded down with authorities are becoming more and more pedantic and absurd. There are no absolute facts in medicine, everything is relative, and good only for the present.

The world is full of working problems, which, like steps on a ladder, are means for higher and wider views of truth. In journalism we get the first surveys, in books, the corrected conclusions, good only for this day and generation.

Medical journalism reflects more and more positively the true spirit of the march of science in this closing century; not the march of science in Germany, France or England, but the movement here in our own country, free from the blighting conservatism of the past, free from time-worn theories, and empiric conceptions that are moss-covered with age and respectability. Free to question every assumed fact, and demand the reasons for its existence.

Medical journalism in this country is growing stronger and more influential every year. We are gaining greater power with every advance, and realizing more clearly that medical science is an incessant search for truth, that widens with every step forward. Both as historians and explorers we are pressing on into the unknown, fully assured that greater facts and truths are yet to come from broad scientific work.

## MEDICAL PROGRESS.

**THE TREATMENT OF INSOMNIA.**—In his concluding remarks in his paper on this subject (read in the Society of Internal Medicine), IAS-TROWITZ, of Berlin, considers the following remedial applications: *Alcohol* may be employed in the form of beer, wine, cognac, etc., and it may be used especially in cases where the other soporific remedies would occasion considerable weakness of the heart. In patients subject to chronic insomnia alcohol should only be used in the light forms of psychical excitement, thus a few glasses of beer may be given at bedtime. Alcohol should be avoided in lypemania and hypochondria, because it increases the morning depression common in these cases.

*Opium and morphine.* I regard the alkaloids as the true soporifics, contrary to the general sentiment, which regards them as simply calming remedies. In spite of the useful action which antipyrin, phenacetin, etc., exert in pain, we cannot ignore the claims of morphine, which has also a tonic action. Thus sportsmen employ it to stimulate themselves, and inject it into their horses to increase their resistance to fatigue. The tonic action of morphine explains its use in the different states of morbid terror and in the insomnia of anæmic subjects. It must be cautiously administered in bronchitis, pneumonia and heart disease. In chronic insomnia it is contraindicated, for the morphine habit is much more difficult to combat than that of chloral, paraldehyde and sulphonal. In certain forms of insomnia—in the senile form, in those which depend upon an intestinal affection, and in chronic lypemania, opium acts better than morphine. Narceine in doses of 0.1 to 0.15 centigrams is a good soporific. Codeine in the same doses sometimes produces convulsions.

*Chloral* is unquestionably the most powerful soporific, but in large doses it lowers blood pressure considerably and paralyzes the heart. Chloral is our best remedy in delirium tremens and epilepsy. According to Liebreich it is contraindicated in diseases of the heart and hysteria. In my opinion it is also contraindicated in cases where there is considerable adhesion of the lungs, as well as in those cases where, after a dose of 4 grams, we do not find that excitement which is manifested in part by contraction of the pupils. In cases where it is active in small doses chloral may be employed to as good advantage in chronic insomnia as in the acute form. It is well to add a little morphine to the dose, for, by retarding the elimination of the chloral, it renders the action of the latter more permanent.

*Paraldehyde* does not weaken the heart, but when employed for a long time it manifests its close relation to alcohol by a chronic intoxication anal-

ogous to the grave forms of delirium tremens. Because of its disagreeable taste and its elimination by the lungs paraldehyde is contraindicated in bronchitis and dyspepsia. It is indicated in hysteria (because its taste is disagreeable), and in icterus accompanied with pruritus. It has also been recommended in cardiac stenosis and rejected in dilatation of the right heart and arterio-sclerosis. Paraldehyde acts very well in insomnia from emotional causes and in epileptic excitement, but its action is less favorable in the four conditions of psychical excitation and morbid fear.

*Hydrate of amyl* is a good soporific free from all danger. It sometimes exerts a bad influence on the stomach, however, and it is then necessary to give it by injection. It has been recommended in typhoid fever, in heart disease, as a remedy for cough (when paraldehyde is contraindicated), and as a soothing remedy in cholelithiasis.

*Sulphonal* enjoys the great advantage of being tasteless and inodorous, which allows its administration without the knowledge of recalcitrant patients. It exerts no influence upon the heart. In acute diseases its action is not sufficiently rapid and it has no influence upon pain. It is, however, an excellent remedy in the insomnia of motor origin, as, for example, in chorea and all forms of mania. I administer it often in small sedative doses during the day and at evening give a large soporific dose. The prolonged use of sulphonal produces a peculiar condition of weakness in the limbs, but unaccompanied by real ataxia. For this reason it is necessary to discontinue its use from time to time.

As regards the inconvenience, danger and intensity of their soporific action, the remedies of which I have spoken may be classified according to the following series: As regards their inconvenience and danger; morphine, chloral, hydrate of amyl, paraldehyde, sulphonal. As regards their efficacy; chloral, sulphonal, hydrate of amyl, paraldehyde, morphine.

Thus we see that *sulphonal* is the least dangerous of all, while at the same time it occupies the second place as regards soporific action.—*Gaz. Méd. de Liège*, July 18, 1889.

**ABDOMINAL SECTION FOR RELIEF OF INTESTINAL OBSTRUCTION.**—PROF. OBALINSKI, of Krakow, in his review of the history of intestinal obstruction, shows that, except for incarcerated hernia, surgical treatment is confined almost entirely to the present century and more particularly to the present decade. He has performed abdominal section in 38 cases of intestinal occlusion from almost every possible cause; of these 15, or 40 per cent., recovered, and excluding 7 hopeless cases, the recoveries would reach nearly 50 per cent. In about 50 per cent. the diagnosis, both as to location and character of obstruction, was proven to be accurate. He insists upon a consid-

eration of the following points in the history of each case: 1, duration; 2, rapidity; 3, number of attacks; 4, predisposing disease; 5, direct cause, traumatic or otherwise; 6, amount of pain; 7, whether pregnant; 8, general condition of patient (whether exhausted or not); 9, form of abdomen—spherical form in obstruction of cæcal, square form, of lower end of colon; marked tympanitis indicates an acute, a slighter amount a chronic attack; 10, marked peristaltic action indicates a mechanical, absence of this a functional obstruction; 11, palpation, recognition of painful spot; 12, vomiting and absence of flatus indicate obstruction but do not locate it; 13, decrease in urine may indicate peritonitis; 14, manual examination of rectum is sometimes useful. With all of these aids a certain diagnosis is possible only in one-third of all cases. In the other two-thirds he advises an *early* exploratory, median incision. If the intestines are much distended they are taken out of the cavity, and in extreme cases a transverse incision is made into the gut, the contents carefully evacuated, the opening closed and the intestine replaced. Whenever possible the obstruction is removed; if not, an artificial anus is made above obstruction.—*Archiv für Klinische Chirurgie*, Vol. 38, Heft. 2.

**A CASE OF INTESTINAL OBSTRUCTION AND GANGRENE.**—DR. W. A. BRIGGS, of Sacramento, reports a case of intestinal obstruction and gangrene. The patient applied for treatment on June 13, 1889, complaining of vomiting and paroxysmal pain. There was no abdominal distension and no tenderness on pressure. On the next day there was stercoraceous vomiting and abdominal pain. The patient had had a similar attack three weeks previously. On the 15th there was less pain, but a tumor had appeared in the right iliac region, accompanied by abdominal distension. On the same day a laparotomy was made. On opening the peritoneum turbid serum welled up and a gangrenous odor was manifested. The peritoneum was inflamed throughout. An elastic tumor of the size of an orange occupied what seemed to be the site of the cæcum; this was formed by a segment of small intestine constricted by adherent bands. A gangrenous segment of the intestine 8 inches in length was found and resected, when it was discovered that there was a second gangrenous tract 6 inches long, separated from the first gangrenous portion by 3 inches of healthy tissue. These two portions were accordingly included in the resection. The bowel was united by a double row of catgut sutures—continuous as regarded the mucous membrane, interrupted as regarded the peritoneum. The mesentery was brought together with interrupted sutures. Patient died in collapse two and one-half hours after the operation. The operator directs attention to the following points: 1. The ease with which death

might have been averted by timely operation. 2. The slight constitutional disturbance prior to actual gangrene. Three days after complete obstruction and two days after the supervention of stercoraceous vomiting, the patient traveled thirty-five miles, and the day after walked two miles. 3. Were the peritoneal bands causing the constriction of so recent origin as the attack three weeks prior to the final one?—*Occidental Medical Times*.

**PHYSIOLOGICAL ACTION OF SACCHARIN.**—PETSCHKE and ZERNER have conducted a series of experiments with saccharin with the object of studying its action upon the organism and its therapeutical effects. Their first investigations concerned its effects upon pytaline pepsin and the ferment of the pancreas. Saccharin in concentrated solution impedes the action of pytaline upon starch because of its acid reaction. If the solution of saccharin be neutralized or if its soda salt be employed the conversion of starch into dextrine and glucose takes place as usual. The action of pepsin is not changed by saccharin, it is merely retarded when in place of using a combination of soda and saccharin the latter is employed alone. Saccharin in powder dissolves slowly and does not allow the pepsin to exert its digestive action until solution takes place. Experiments upon the living subject show that saccharin in doses of from 0.05 to 0.30 grm. exerts no influence upon digestion. In doses of from 0.50 to 1 grm. it retards digestion when taken pure; its soda salt, which is more soluble, may be taken even in doses of 5 grm. without disturbing digestion. The action of saccharin on pepsin is *nil* when its soda salt is used, while saccharin in substance exerts an unfavorable action, because of its acid reaction. Petschke and Zerner reach the conclusion that saccharin should not be employed except when combined with soda. As a substitute for sugar saccharin may be taken for a long time without impairing the appetite or the patient's well-being. Saccharin is eliminated by the urine, but not by the saliva.

From a therapeutic standpoint Petschke and Zerner have employed saccharin in 50 cases, in doses of from 0.1 to 10 grm. Its antipyretic action is almost *nil*, as estimated by the action of the pulse, respiration and transpiration. They have never observed the supervention of albuminuria after the administration of saccharin even in invalids predisposed to nephritis. The antizymotic action of saccharin is especially manifested in cases of abnormal intestinal fermentation. No specific action of the remedy has ever been noted in any disease. In cystitis saccharin exerts no influence. In two cases of *otitis media purulenta* which resisted the action of boric acid the otorrhœa was cured in a few days. The most decided successes have been witnessed in dys-

pepsia and gastric disorders produced by abnormal fermentation. In doses of from 0.3 to 1 grm. every two hours, combined with irrigation of the stomach, saccharin soon ameliorates all symptoms of fermentation, which however reappear as soon as its administration is suspended. In diabetes the employment of saccharin, together with a suitable regimen, is soon followed by a rapid diminution of the quantity of sugar in the urine.—*Gaz. Méd. de Liège*, July 18, 1889.

**DIABETES MELLITUS AFTER EXTIRPATION OF THE PANCREAS.**—J. V. MERING and O. MINKOWSKY have made, in the laboratory of the medical clinic in Strassburg, a number of experiments the results of which are given by them as follows: Diabetes mellitus occurs in dogs after extirpation of the pancreas. It begins some time after operation and continues for weeks, without interruption, until death. Besides sugar in the urine, there was polyuria, intense thirst, excessive appetite, acute emaciation and debility despite abundant nourishment.

A dog, whose pancreas had been removed, and which had eaten nothing for 48 hours, passed urine containing from 5 to 6 per cent. of sugar. Another dog 8 kilogr. in weight, which was given nothing but meat, passed almost one liter of urine containing from 5 to 6 per cent. of sugar, every day. After adding grape-sugar to the food the proportion increased temporarily to 13 per cent., by far the larger portion of the sugar added to the food being excreted unchanged. It may also be mentioned that the urine of the animals operated upon contained noticeable quantities of acetone.

The proportion of sugar in the blood is largely increased; in one case it amounted to 0.30 per cent., in another 0.46 per cent. Glycogen disappears from the organs; it could be found neither in the liver nor in the muscles of a dog that had been diabetically affected for four weeks and was killed while digesting meat.

The solar ganglion was not injured in the operation, the diabetes being a direct result of the extirpation of the pancreas. Transfusion of blood from a diabetic dog into the veins of a healthy animal did not cause sugar-excretion in the latter. Finally, in animals without pancreas the resorption of fat is greatly impeded, the utilization of the albumen also seeming to be very imperfect.—*Centralblatt für Klinische Medizin*, No. 23, 1889.

**ENURESIS.**—DR. RICHARDS recommends a combination of bromide of potassium and tincture of belladonna in nocturnal incontinence. He reports two immediate cures in boys of 12 years where the affection had lasted from infancy. Ten grains of the bromide and fifteen or 20 minims of the tincture were given at night.—*British Medical Journal*, June 22, 1889.

SATURDAY, SEPTEMBER 7, 1889.

THE TREATMENT OF LOCOMOTOR ATAXIA BY  
SUSPENSION

Seven years have passed since Motchoutkowsky, of Odessa, after using Sayer's apparatus for the application of a plaster jacket to an ataxic patient suffering from Pott's disease, observed an improvement in the symptoms of his patient. Although he published, in the following year, the results of this treatment in sixteen cases of tabes, claiming favorable results in all but two, it was not until Charcot, in January of the present year, lent the weight of his authority to the method, that it attracted any general attention. Since then, observations have multiplied, and it may be considered the fashionable treatment. Although the status of any therapeutic measure in a disease of so protracted and irregular course can only be determined after much more prolonged observation than has been had in most of the cases thus far treated, the reported results have been, temporarily at least, so generally favorable, and the difficulty and risk of the treatment, under proper precautions, are so slight, that it would seem worthy of a general trial.

The only extensive statistics thus far published are those of Charcot, who had, in March, 1889, treated 114 cases of tabes by this method. Of these, sixty-four did not remain long enough under treatment to determine its effects. Of the remaining fifty, thirty-eight were decidedly benefited, seven unimproved, and in five cases, the effects were injurious.

In favorable cases, nearly all the troublesome symptoms of the disease are said to disappear,

wholly or in part. Coördination, sensibility and sexual power improve; control over the bladder is regained; lightning pains cease. The patellar reaction does not seem to have been recovered in the reported cases, and the degree of improvement varies greatly. It is not usually noticeable until the eighth or tenth suspension, and may be delayed as late as the twentieth. The permanence of the improvement must, for the present, be considered uncertain, although one of Motchoutkowsky's patients is said to be able to take long walks five years after the cessation of treatment.

The rationale of the treatment is not very evident. Experiments have shown that in the cadaver, at least, the vertebral canal is sufficiently elongated to exert slight traction upon the spinal cord by the nerve-roots, but why this should be beneficial is not clear. Althaus suggests that it may be due to the breaking up of adhesions in the meninges and neuroglia. For the present, the method must be considered empirical rather than scientific.

In view of the fact that two persons who have attempted to conduct the treatment on their own persons have died from asphyxia, and that death has occurred, apparently as the result of suspension in two other cases where it was practiced without medical supervision, it would seem advisable that when undertaken it should be conducted by the physician, and begun with caution. Pulmonary, cardiac and vascular disease, great debility and anæmia are held to be contra-indications.

It is probably not well to be too sanguine in our hopes from this or any other treatment. The operation of nerve-stretching for the same affection is not quite forgotten, although it seems to have passed into "innocuous desuetude" and the inflation treatment of phthisis seems to have pretty thoroughly collapsed. If even temporary comfort can be given to any large proportion of the sufferers from this disease, it will be a great boon to both physician and patient, and, so far, mitigate what has been one of the opprobria of medicine.

MEDICAL PERIODICALS.—It has been ascertained that the principal medical periodicals of the world number 266; 174 are published in the United States and 92 in all other countries.

## A NEW DISCOVERY.

The successful disposition of sewage is the question of all-absorbing interest in nearly every large city in the world. Nowhere, perhaps, has there been a greater need, nor has the subject received elsewhere more able and critical study than in the city of London. Up to the date of the last month the royal commission on metropolitan sewage discharge have been unable to report any feasible plan for the purification of sewage by precipitation.

A MR. WOLLHEIM, of London, now claims to have discovered a method by which this result may be successfully accomplished. He utilizes certain organic bases belonging to the group of ammonia compounds in combination with lime. As the result of chemical reactions, a gaseous reagent is evolved to which he gives the name of "amminol." It is a powerful disinfectant and, as stated in the *London Times*, when introduced into sewage rapidly extirpates all microorganisms capable of causing putrefaction or disease. When thoroughly intermixed with sewage the effect is almost instantaneous, the putrid odor of the sewage being at once replaced by that of the reagent. In thirty minutes the liquid portion of the sewage can be discharged deodorized and sterilized with perfect safety.

According to reports made by DR. KLEIN, F.R.S., the disinfection as well as the deodorizing is complete. He states that a sample of sewage examined by him contained 2,400,000 organisms in a cubic centimetre, and that the affluent after treatment was absolutely free from all or any organisms. Dr. Klein suggests that the effects of the treatment on specific microorganisms such as bacillus anthracis, the cholera comma bacillus, the typhoid bacillus, the pneumonia bacillus, should be ascertained. We shall watch with special interest for the verification of Dr. Klein's experiments. If this new discovery can be utilized successfully it may prove to be one of the most important achievements of the present age. And if its germicidal power can be utilized in the destruction of the microbes producing specific diseases its value may be beyond any possible estimate. Its claim to our confidence will be absolute when this is fully verified.

## A FORLORN HOPE.

His experimental work in previous years had

been such as to gain for the name of BROWN-SÉQUARD a prominent and permanent place in medical literature. In view of the reputation which he had thus worthily achieved, it is not singular that any views put forth by him should command immediate and critical attention. Again, he could hardly have struck a more responsive chord than when he gave assurance that the secret of perennial youth was at his command. If at last the dream of the poet and theme of the muse were to be realized, when age would be able at pleasure to take on its youth, what name or what claim could in a day command more world-wide attention. This alone is sufficient to account for the immediate and universal discussion of this question by pen and by press, by saints and by sinners alike.

But the possibility of immediate rejuvenation is so utterly at variance with all known laws, either biological or physiological, that we can only regard such a promulgation as the senseless vagary of one, enfeebled by age, and beyond question in present and pressing need of such rejuvenation. His utterances have seemed to us too absurd to warrant serious consideration in the columns of *THE JOURNAL*. For this reason we must decline to publish a score or more of letters, many of them witty and some of them wise, all bearing upon this same subject. We can by no means indulge this forlorn hope of life renewal.

In this connection we desire heartily to commend the forceful and timely utterances of the *Medical Record* in its issue of August 24 and the experimental study of the subject, as conducted by PROF. LOOMIS, and published in the same number of the *Record*, could hardly have been committed to better hands. But we confess to no little surprise that with such results as are there detailed Prof. Loomis should have reached such conclusions.

For the time, no doubt, the subject will command very general attention, and be seized upon by some as a stepping-stone to personal notoriety, and as a means of cheap advertising. For a time the victims of injudicious and unwarranted experimentation will suffer the penalties which are sure to follow, but later this theory also will be numbered with the delusions of the past, and the name of Brown-Séquard will hardly receive additional honor by reason of such connection.

## BRAIN SURGERY.

DR. EDMOND SOUCHON, of New Orleans, has demonstrated by experiments on dogs a useful and, as it seems, a safe method of exploration of the brain for the purpose of locating pus cavities. To obviate the necessity of removing a large button of bone, as is usually done, by means of the ordinary trephine, he employs a watchmaker's drill, which makes an opening just large enough to admit a needle with a calibre about twice the size of an ordinary hypodermic syringe. This method permits one to make several tentative punctures with the infliction of comparatively little injury. In his experiments he made use of dogs, in which he found that four such operations of trephining and puncture, in a single animal, were unattended by noticeable effects. After the results of the first operations were obliterated the animals were kept at rest for two weeks, when the same operations were repeated, with similar results—no remote effects whatever being witnessed.

## EDITORIAL NOTES.

## HOME.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE is now in session at Toronto.

THE AMERICAN ACADEMY OF MEDICINE will hold its annual meeting at Chicago on the 17th and 18th inst.

THE NATIONAL ASSOCIATION OF DENTAL FACULTIES at their recent meeting at Saratoga adopted the three-term course in all Colleges of the Association. This rule will go into effect after the session of 1891-2, and the terms not less than five months each.

MONEY FOR THE JOHNS HOPKINS UNIVERSITY.—The will of John W. McCoy, recently admitted to probate, makes the Johns Hopkins University the residuary legatee and bequeaths to that institution \$100,000. Mr. McCoy also leaves it his magnificent library, and gives to the Peabody Institute his collection of paintings. The rest of the estate, about \$150,000, is divided up among literary friends.

A CORRECTION.—We notice that a number of our contemporaries are publishing a statement to the effect that typhoid fever is epidemic in Chicago.

It is simply a misapprehension of facts. The only fever that Chicago is troubled with just now is the World's Fair Fever! It seems to have spread already beyond the limits of ordinary sanitary control, and evidently Congressional legislation will alone be equal to the emergency. We hardly look for its subsidence before the close of 1892.

SURGEON HARVEY E. BROWN, U. S. A., died August 20, at Jackson Barracks, near New Orleans. He was a son of Gen. Harvey Brown, of the regular army, and born in New York. He graduated from the University medical department in 1858. He was surgeon of volunteers from 1861 to 1863, and then became Assistant Surgeon, U. S. A.; became full Surgeon and Major in 1881. He was the author of a valuable compilation and historical sketch of the Medical Department of the Army from 1775 to 1873. He was identified with nearly every epidemic in the Gulf District for twenty-five years. His final disease was lingering and painful, due to consumption.

DR. HOLMES AT FOUR SCORE YEARS.—A despatch to the daily press says that Boston's typical son, Oliver Wendell Holmes, celebrated his 80th birthday on the 29th ult., and despite its informal character the anniversary was a most charming one. He spent the days at his summer home at Beverly Farms. This is a quiet place, liberally embowed in vines and flowers, and most suited to such a festival. The flowers outside the house were nearly equaled by those within, the gifts of friends, which had been sent in the early morning. From nine o'clock throughout the day until night fall there was a continuous succession of visitors, mainly from the neighboring north shore estates. The doctor, seated in his comfortable library, with his attractions and alluring furnishings, received all his friends with a bright and pleasant smile and hearty cordiality. His surroundings added much to the charm of the occasion, the room being a genuine old-fashioned study of the kind our grandfathers loved, with a tall, quaint firescreen and open fireplace with its blazing logs resting on the ancient firedogs, whose polished brass standards reflected the careful housewife. The floor was covered with neat canton matting and a mammoth rug spread out before the fire. In one corner was a simple rolltop desk and in another a book-case

with the doctor's favorite authors convenient for ready access. The chief charm of the entire interior was its thorough homelikeness.

One of the many pleasant features of the day was the coming of the children. In the forenoon the boys and girls of Beverly Farms school to the number of twenty-six called in a body, and were given a most cordial reception, the doctor entering heartily into the feelings of his little friends, giving each a warm shake of the hand and his friendly smile. To each he presented a pretty bonbonnière filled with sweets, tied with a bright bit of ribbon, and bearing on its cover a miniature vignette of the poet, with his name beneath. The children of the neighborhood came in the afternoon, and the lovely, shaded roads and bypaths were filled with white clad little maidens going and coming. Besides flowers there were many other pretty souvenirs of the anniversary. Among them was a handsome cup, presented by lady friends of the doctor. It bore the following motto:

..... AUGUST, XXIX, MDCCCLXXXIX. ....

" 'Tis the heart's current lends the cup its glow,  
Whate'er the fountain whence the draught may  
flow."

..... —*Oliver Wendell Holmes.* .....

The pledge of friendship.

The cup is of silver, lined with gold. During the day letters of congratulation were received from J. G. Whittier, George William Curtis, Charles Eliot Norton, and a large number of others.

**A NEW TRI-STATE MEDICAL ASSOCIATION.**—The following call has been issued by Frank Trester Smith, M.D., Chattanooga, Tenn., Secretary of Committee: "The members of the medical profession in Alabama, Georgia and Tennessee are requested to meet in Chattanooga on the third Tuesday in October, for the purpose of forming a Tri-State Medical Association. All will be admitted to the meeting of the Association, but the membership will be restricted to graduates of regular medical colleges in good standing."

This call is signed by committees from Jackson County, Ala., Medical Society; Chattanooga, Tenn., Medical Society; Cleveland, Tenn., Medical Society; Cartersville, Ga., Medical Society; Dalton, Ga., Medical Society. It is hoped that there will be a general turnout of the profession.

Papers of interest have been promised by prominent men.

This organization will be independent of all other societies. It will be an association of individual members of the Profession of Medicine, and will be managed in the interest of medical progress. The session will continue two days. Those desiring to read papers or exhibit specimens should notify the Secretary at an early date.

A circular will be issued in due time announcing the titles and authors of papers.

**THE ONTARIO MEDICAL LIBRARY ASSOCIATION**, at Toronto, is in its second year. It is energetic and ambitious. The cataloguing will be done on the plan of the Index catalogue of the Surgeon-General's Office at Washington. The trustees have established a bureau of nurses, and during the current year they expect to publish a complete physician's register for the city of Toronto.

**DEATH FROM NICOTINE.**—A case of excessive cigar smoking, followed by death, is given by Dr. B. W. Richardson in *Asclepiad* for May. A man, aged 35 years, of slight build, much worried by the cares of business, indulged in smoking almost continuously for twenty-four hours, and taking nothing but a little brandy and water. Within a period of twelve hours he smoked fourteen large strong cigars and forty cigarettes. He became prostrated, excited and tremulous, with loss of muscular power in lower extremities. At this point, the author was called in. Supporting treatment was ordered, but without avail; the loss of muscular power increased and extended to the upper part of body. Unconsciousness and convulsive symptoms set in and increased until the evening, when death took place by asphyxia, through accumulation of fluid in the bronchial passages. The author traces these conditions to nicotine poisoning. He concludes by stating that if he has to deal with another case of this nature, he will try the effects of transfusion.

**DR. D. TILDEN BROWN.**—The *New York World* of August 25, contains an interview with Dr. D. Tilden Brown, formerly at the head of the Bloomingdale Asylum, New York, who has been reported to have died in Europe. Dr. Brown is now farming and practicing in a limited field, a few miles distant from Chicago. There are a host of

former friends of Dr. Brown who will rejoice that he is alive and well, and that they need no longer speak of him as "the late Dr. Brown."

**THE WATER SUPPLY OF PHILADELPHIA.**—The *Philadelphia Inquirer* is responsible for the following: It states that it has caused a new investigation to be made concerning the alleged contamination of the Schuylkill River, which is one of the sources of the water supply of that city. It makes the statement that the river is "little better than an open sewer," since almost the whole distance from the coal mines to the Fairmount Waterworks may be found abundant agencies for pollution, in the unguarded admission of the drainage from hundreds and thousands of houses, farms and factories. The *Inquirer* makes an estimate that there is a population of not less than 250,000 persons, whose drainage more or less contributes to the fouling of the stream which gives drinking-water to a million of people. The onset of typhoid fever has been fully a month earlier than in most former years; there having been already reported more than 400 cases.

**RUSH MONUMENT COMMITTEE.**—We have received the following communication to which we invite the special attention of our readers: At the meeting of the Rush Monument Committee, held at Newport, R. I., on the 26th of June, last, Dr. D. C. Patterson, of Washington, D. C., was elected Treasurer, vice Dr. J. M. Toner, on nomination of the latter, who asked to be relieved of this portion of his duties as member of the Committee.

Notice is also given that the limitation of contributions having been removed sums of any amount will be received, and it is earnestly hoped that the enthusiastic and unanimous approval of the projected monument at the Newport meeting of the Association will find expression in prompt and liberal remittances, which should be addressed to DR. D. C. PATTERSON, *Treasurer*, 919 I St., N. W., Washington, D. C.

ALBERT L. GIHON, M.D., *Chairman*.

GEORGE H. ROHÉ, M.D., *Secretary*.

**MISSISSIPPI VALLEY MEDICAL ASSOCIATION.**—Our reader will bear in mind that the annual meeting of this Association will be held at Evansville, Ind., on the 10th, 11th, and 12th inst., and rates have been placed at a fare and a third on all the roads centering at that point.

#### FOREIGN.

PASTEUR is now a baron and Edison a count.

THE EMPEROR OF AUSTRIA is establishing sterilizing apparatus on a large scale for the gratuitous preparation of milk for the children of the poor.

**COOKING BY ELECTRICITY.**—The *Scientific American* says: The Hotel Bernina, at Samaden, has for some time been lighted with electricity, power being supplied by a waterfall. As during the day the power is not required for lighting, and is therefore running to waste, the proprietor of the hotel has hit upon the idea of utilizing the current for cooking when it is not required for lighting, and an experimental cooking apparatus has been constructed. This contains German silver resistance coils, which are brought to a red heat by the current, and it has been found possible to perform all the ordinary cooking operations in a range fitted with a series of such coils.

IN GREAT BRITAIN Dr. E. McDowell Cosgrove has been appointed physician to Mercer's Hospital, Dublin. There are upwards of 140 writers on the editorial staff of the *British Medical Journal*. The Prince of Wales is still suffering from a gouty affection of the leg. The citizens of Perth are agitated over a possible contamination of their water supply. Scarlet fever is prevalent in Birmingham.

**DIET IN CASES OF FOREIGN BODY IN THE ALIMENTARY CANAL.**—At a recent meeting of the Société Vaudoise de Médecine, Dr. Roux, of Lausanne, communicated the case of a woman who, having undergone Schoenborn's plastic operation on the soft palate (destroyed by syphilis), swallowed a curved needle fixed in the retro-pharyngeal flap. She was treated by feeding with potatoes alone, in large quantities, with the result that the foreign body was discharged with feces on the third day, without having caused any unpleasant symptoms from the first to last.—*British Medical Journal*.

**COMPULSORY NOTIFICATION.**—Dr. A. C. Munro, in the London *Lancet*, presents data showing that in the little town of Jarrow, England, the system of compulsory notification has been the means of saving, during the last ten years, an average of eighty lives and 1,000 cases of sickness per annum.

## TOPICS OF THE WEEK.

## THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION. ENDORSEMENT OF THE BRITISH MEDICAL JOURNAL.

The recent meeting of our associated *confrères* across the Atlantic was a success, both in attendance and in the character of the work presented. The eminent gentlemen who were selected to prepare the addresses fulfilled their tasks admirably. We regret that our space does not permit us to publish these addresses in full, but we hope to be able from time to time to make such selections from them as will be of interest to our readers.

The financial statement of the Treasurer of the Association showed an increase in receipts of £3,105 over 1887, and an increased expenditure of £1,169. In view of the balance in hand for the year, amounting to £4,000, it was decided to send *The Journal* to the Colonies and India postage free.

Dr. Bridgwater, the President of the Council, in moving that the Report of the Council be adopted, eulogized the Editor and the General Manager for the able manner in which they had conducted *The Journal*, and replied to the critics in such a manner that the report was unanimously adopted.

Dr. Bridgwater also laid before the meeting a letter from Sir Joseph Lister on the conduct of *The Journal*, together with his reply thereto, and the resolution passed by the Council, as follows:

*To the Council of the British Medical Association.*

LONDON, AUGUST 1, 1889.

GENTLEMEN:—Many members of the Association have been much disappointed to find that the hopes which they had been led to entertain of an improvement in the conduct of *The Journal* have not been fulfilled. So strong is this feeling that a large number of men in influential positions in the profession, warmly attached to the Association, but jealous of its honor and despairing of seeing the improvement they desire, have expressed their determination to resign their membership.

But before carrying into effect a resolution so serious, it has been thought right to approach you, as the governing body, with the request that you will give this matter your earnest consideration, and take such steps as shall make *The Journal* in all respects worthy of the Association which it represents. We have the honor to be, gentlemen, your obedient servants.

(Signed)

JOSEPH LISTER, Chairman,  
W. H. ALLCHIN, )  
W. A. MEREDITH, ) Secretaries  
JOHN WILLIAMS, )

*Reply of President of Council.*

DEAR SIR.—I beg to acknowledge the receipt of your letter dated August 1. I will lay it before the Council when they meet in Leeds next week. I must be permitted, meanwhile, to assure you that you may safely leave the honor of the Association where it has been safely preserved for so many years. Yours faithfully,

(Signed)

T. BRIDGWATER.

*Resolved.* "That the Council do not admit that the signatories of this letter are better judges than themselves, or more solicitous than they are for the honor of the Association and of the profession but if there are any points which the signatories desire to particularize, in which they consider that *The Journal* admits of or calls for improvement, they will, as they ever have been, on receiving them through the Representatives of their Branches in the Council, be ready to give such suggestions their careful consideration."

Mr. Lawson Tait then moved the following resolution, which was carried with only one dissentient:

*Resolved.* That this meeting desires to express its satisfaction with the result of the present representative system of government of the British Medical Association, and their approval of the steps taken by the Council for the management of *The Journal*.

## THE MENTAL HYGIENE OF PHYSICIANS.

In a presidential address delivered at the Medical Alumni Association of the University of Michigan, June 26, 1889, Dr. E. P. Hurd considered at length the subject of "The Mental Hygiene of Physicians." The address is able and eminently practical. At the expense of other matter we give space for its conclusions:

"If physicians would retain good mental health and intellectual vigor sufficient for the discharge of their varied duties in the best possible manner they should avoid:

"First, Overwork and the train of physical and mental symptoms which accompany it. To this end they should systematize their work, and as far as possible perform every duty at its proper hour. Office hours should be kept scrupulously; hours for meals, for sleep and for recreation should be as scrupulously observed. If a call comes which destroys the rest for a single night the lost sleep should be made up as fully as the circumstances of the case will permit. Much of a physician's time is frittered away by duties and occupations which are foreign to his true work. Guard your time sedulously from needless interruptions. Work done amid constant interruptions is always performed at an increased expenditure of nervous energy. The mind works best in accustomed grooves. When your attention is claimed by half a dozen different topics in as many moments the transition from one to another is always accompanied by a mental wrench which is detrimental to good work. Every physician should secure an annual vacation and relinquish toil altogether even if it is only for a single day.

"I am aware that plan we never so wisely overwork is sometimes inevitable, and an injurious strain upon the physical and mental forces is frequently unavoidable. The physician becomes sleepless, loses appetite, fails in strength, and shows other signs of exhaustion. Shall he at such a time spur on his jaded energies by stimulants or relieve his disagreeable sensations by narcotics? It were suicidal for him to do so. A stimulant or a narcotic may temporarily whip up the exhausted energies, but at the expense of more serious disaster later. The real remedies are rest and nutrition. Physicians should live well and avoid exhaustion by making a special study of foods and their effects upon themselves when suffering from exhaustion. A cup of cocoa, a glass of milk, a cup of bouillon, or coffee, will do as much as a stimulant, and more, because food is thus supplied in addition. The vexed question of tobacco has a bearing upon this point. If the narcotic it contains is promptly eliminated by the system and the indulgence leaves no unpleasant taste in the mouth, an occasional cigar or semi-occasional pipe may prove of benefit. For the sake of example let me suggest that smoking be done surreptitiously in the privacy of home or the sanctity of the inner office, far from the gaze of the curious, because in my judgment it cannot be denied that non-medical men who do not smoke

from such pure motives, but merely because they enjoy smoking and without any ulterior considerations of health are generally injuriously affected by the indulgence.

"*Second.* The social side of the physician's life should be cultivated. He should attend social gatherings, balls, picnics, lodges, churches, everything which will bring him into contact with his fellow men in a non-professional way. I know by experience how difficult it is for a physician to meet his fellows non-professionally. The hypochondriacal patient who desires an opportunity to talk over his symptoms gratuitously with a physician, the busybody who is so much gratified to have an opportunity to discuss the ailments of some one else and wring a prognosis, favorable or otherwise, from the family physician, the professional philanthropic who is sure to ask you what to do for half a dozen of his poor dependents—these and a hundred others conspire to rob the physician of any change of occupation even when he goes among his fellow men for social purposes. Do not hesitate to shake off these men. They are sponges not worthy of consideration and should not receive any. Dismiss them in the same category with the man who stops you in the street to inquire what is good for rheumatism or what he shall do for a cold. Many physicians finding their best efforts to meet the world socially, failures, by reason of unforeseen interruptions and untimely calls fall into the habit of accepting social deprivation as an inevitable lot. Do not yield thus, but make a diligent effort to break through the growing habit of indifference. Meet your friends and neighbors socially as often as you can.

"*Third.* Avoid the danger of looking wholly at the material side of vital phenomena. Human life is not solely the result of organization and cannot be explained satisfactorily from a consideration of its constitutional atoms. Vital growth, vital-action, the beginning of life, the onset of death, all imply something that is beyond mere material organization. From the standpoint of many physicians, as far as material organization is concerned there is little or no appreciable distinction between a Washington or a Lincoln or a Benedict Arnold. There were, however, hidden spiritual forces in the material organization of the former which rendered them a blessing to the world, and in the other a lack of it which has made the name odious. There is something in each man above, beyond, and higher than his physical organization. If vitality were but the result of organization medicine ought to be an exact science. No one knows better than we do how unlike the chemical crucible or the retort the body of man is, and how uncertain its reactions are. Life is God-given—a spark from Deity. Such views enable our profession and give us new zeal in the discharge of duty.

"*Fourth.* The life of the true physician is a practical religion. It is full of self-sacrifice and zeal for the welfare of others. It is a perpetual sacrifice of inclination to duty. The welfare of the patient is the first consideration, the comfort of the physician the last. Little needs to be added to the ethical side of the true physician's character. There should be added to this, however, a

belief in an over-ruling Providence personally interested in the affairs of men. This trust and confidence in the arrangement and disposition of human affairs by an all-wise Creator should be cultivated by every physician. Nothing is better calculated than such a belief to remove the unfortunate habit of worrying over the untoward results of disease. Death should not be looked upon as necessarily due to your neglect to do this or your failure to do that. 'Having done all' in his power to stay disease the physician should 'stand fast' in his own rectitude. He knows he has done the best he can under the circumstances—possibly not the best that could have been done absolutely, but the best he could do with the knowledge he had when he proffered his advice, or gave the medicine, or treated the patient. Nothing helps so much in bearing such cares or responsibilities as a genuine trust in a Higher Power and an Over-ruling Providence.

"*Fifth.* Allied to this, and growing out of it, is the necessity of cultivating a cheerful, hopeful spirit for the physicians own good. The absolute necessity of such cheerfulness and hopefulness on the part of every physician in the sick-room is obvious. If 'Christian Science,' so-called, has met with any success, it is because of its constant inculcation of hopefulness upon the invalid. 'You are not sick.' 'You are well.' 'You only have a mistaken idea of sickness,' etc. Such are its formulæ, which often are unmeaning enough, and yet which appeal powerfully to a most potent agency in the treatment of disease. I did not, however, design to speak of this aspect of the matter as much as of the duty of cheerfulness for the physician's own good and for the preservation of his own mental health.

"*Sixth.* Occupation, professional and otherwise. Every physician should have some subject for special study—Some hobby if you chose to call it so—all absorbing in its character, into which he can retire and forget for the time being the cares and annoyances of his daily life. This should be some branch of medical study in which he is an original investigator or a special student. I recognize the fact that we do not all possess the required talent to make deductions from observations carefully collated and recorded, but all have the ability to do the latter and to gather and arrange scientific or medical facts for master minds to interpret. The effect of such individual investigation upon the physician who makes them will be inestimable. When thus engaged he has a kingdom of his own into which he can enter without fear of intrusion—a city of refuge from the world without. The influence of such special investigations upon the profession at large in promoting knowledge and unifying effort would be incalculable. There are numerous branches of medical knowledge where careful, painstaking, personal observations such as any practitioner can make no matter where he may practice, are required to give better indications for treatment. I refer to certain anomalous forms of fever which are nowhere adequately described in any text-books; the action of remedies, new or old, upon different organs of the body; the relations of certain eruptive fevers and the laws of their development; the causation of pneumonias by atmos-

phic conditions; the phenomena of hypnotism, and the like. These are but samples of subjects concerning which every thoughtful physician can furnish original and valuable contributions to our stock of knowledge, provided he has formed the habit of observing accurately and recording carefully what he has seen. Beyond this, every physician should have a pursuit or study, wholly outside of medicine, to serve as a diversion and means of recreation. In choosing such pursuit, it should not be forgotten that the medical is one of the learned professions. Hence, the pursuit should be allied to medicine and calculated to increase one's zest for medical study or to throw side lights upon it. Botany, comparative anatomy, microscopy, photography, etching, drawing or sketching, meteorology, hygiene, natural history, modern languages, these are a few of the studies which many physicians are constantly pursuing. I have read with great interest, but recently, of the vigor and enthusiasm with which the lamented Douglass Houghton, the second professor appointed to a chair in this University—the first professor being the late Asa Gray, of Harvard—prosecuted the study of chemistry, botany, and geology, while pursuing the active practice of medicine in the city of Detroit. Such studies keep the mind active, and furnish diversion and needed recreation. They help to get our minds out of routine pursuits, and enlarge our ideas, and broaden our mental horizon. The intense man who is constantly applying himself to a single pursuit is much more likely to lose his mental health, than one whose energies have been diverted into several channels.

"*Seventh.* Avoid professional jealousies and heart-burnings. They come too often from the feeling that pecuniary returns are the proof of professional success, and from unworthy and ignoble views of the profession itself. Medicine should not be pursued as a trade—a simple means of livelihood, a stepping-stone to wealth, but as a learned profession, a true vocation, requiring the largest mental acumen, the keenest insight, the most rapid generalization, often from insufficient data, and the broadest mental grasp of any profession. The mission of the physician is not to make money, but to relieve suffering, to help Nature in her efforts after health, and to lay the foundation for the future Science of Medicine, which is surely coming. Every physician should comfort himself, amid doubts and discouragements, by the ancient motto, 'It belongs to all to deserve success, not to attain it.' All can deserve the character of a good physician, even if the emoluments of the profession are not theirs, and pecuniary success is uncertain. Professional jealousies and sharp competitions are unworthy the man who possesses this high ideal of his calling. The soured, disappointed, cynical, embittered physician has mistaken his calling.

"*Finally:* If we would retain good mental health, we must not lose faith in the future of our noble profession. The great advance in every department of medical science during the past twenty years, leads us to anticipate most encouraging developments in the near future. We are on the threshold of a new era. Nature is yielding her secrets to patient inquiry. Mystery is becoming certain knowl-

edge and assured truth. The future of medicine is inspiring. The thought of it richly solaces us for temporary disappointments and seeming failures. Let us be content to be humble laborers in the erection of the great edifice of scientific truth and accurate knowledge, which is rising before us."—*Physician and Surgeon*, July, 1889.

#### GASTRIC ULCER.

Dr. Longfellow, of Cincinnati, gives in the *Lancet-Clinic* a formula which he has used in gastric ulcer with very satisfactory results:

R		
	Liq. potass. arsenit. . . . .	5j
	Tinct. opii deod. . . . .	5ijss
	Acid hydrocyanic, dil. . . . .	5jss
	Aquæ destil. q. s. ad. . . . .	5iv

℞  
Sig.—One teaspoonful every three hours, after taking milk.

Minute doses of cocaine have at times been indicated, and combined with the above, with the result of decided relief of pain. All starch and sugar foods are to be withheld.

Dr. Stepp, of Nuremberg, according to the *Lancet*, has employed chloroform internally with good effect. He prescribes it in the proportion of "15 grains in a 5-ounce bismuth mixture." He regards it as beneficial by reason of its disinfecting, astringent and stimulating properties.

## SOCIETY PROCEEDINGS.

### Medical Society of the District of Columbia.

*Stated Meeting, February 20, 1889.*

CHARLES E. HAGNER, M.D., PRESIDENT,  
IN THE CHAIR.

DR. D. S. LAMB presented

#### TWO SPECIMENS OF CHRONIC OSTEITIS.

In one case the right tibia is much enlarged by sclerosis, with a central abscess cavity; medullary cavity almost entirely obliterated. Abundant exostoses. From a colored man, aged 60, who died of chronic diarrhea. The post-mortem examination showed some fatty degeneration of mitral valve and some atheroma of aorta; heart weighed 13 ozs. Liver congested. Spleen atrophied. Colon deeply ulcerated throughout. A few small cysts of kidneys. Prostate enlarged. No history of injury.

The second specimen showed sclerotic thickening of lower part of femur, with large exostoses (osteophytes). Upper part of corresponding tibia porous. Some ulceration and exostoses in knee-joint; and patella firmly ankylosed to front of femur. From colored man, aged 70, who had inflammation of knee-joint when 15 years old. When 62 years old abscesses formed

around the joint and were opened. He had also chronic ulcers of tibia.

DR. C. W. RICHARDSON read a paper on

AN INTERESTING TOXIC MANIFESTATION  
OF COCAINE.

The interesting case of cocaine toxæmia which I am about to narrate is for the purpose of calling the attention of many to a hitherto unheard of toxic manifestation of cocaine, and impress upon those who are already acquainted with this peculiar effect the possible danger which may arise from the incautious and somewhat careless manner with which this drug is frequently administered. Many of you are no doubt aware that cocaine is capable of unduly exciting the sexual passions; but few, probably, are aware of its capability, like ether, of exciting undoubted objective erotic manifestations.

During the month of October, 1888, it was my intention to operate upon a certain woman, in order to remove from the left nasal cavity a cartilaginous spur projecting from the septum, which was pressing upon the inferior turbinated body, giving rise to certain nervous phenomena and complete obstruction of that nasal cavity. The object of the operation was to restore the calibre of the passage and to prove the dependence of the nervous symptoms upon the existing deformity. She was a well-developed, well-nourished woman of 25; married; had had one child; large physique; handsome, modest and reserved. After explaining to her the nature of the operation and possible relief to be obtained she readily assented to its performance. On the day appointed she reported, being accompanied by a lady friend. Before operating my patient told me that she expected to be sick on the morrow, but did not wish to have the operation delayed unless necessary. In order to make the operation as painless as possible, experience having demonstrated the fact that cocaine applied locally has very little effect in rendering operations upon the septum painless, I concluded to administer hypodermically directly into the tissue to be removed a few minims of a 10 per cent. solution. Five minims of 10 per cent. is equivalent to one grain of the drug. After using the injection, for a moment, I gave no further heed to my patient, as I little anticipated the rather unpleasant results that followed my injection. My attention was suddenly attracted, and to my surprise, and the consternation of her companion, the patient began to manifest the most remarkable and decided evidence of erotic excitement. It is entirely unnecessary for me to give a résumé of her actions, facial and verbal expressions—her objective demonstrations were unmistakable. It required some time to bring her to even a moderate degree of quietness. As quickly as possible I removed her, with the assistance of her friend, from the

chair on which she was sitting to a sofa. While reclining she made incoherent remarks; called frequently for her husband; and kept her head in almost constant motion. Afterwards she walked the floor, wrung her hands and gave other evidences of great excitement. She states that she had no unpleasant sensations in connection with the circulatory or respiratory system; no faintness, heaviness; or wakefulness. She retired on going home, and when I saw her, at eight in the evening, she was in a normal condition. A few days afterwards I attempted again the removal of the spur, being on this occasion assisted by Dr. H. B. Deale. In this attempt I used my cocaine, not only in a local manner, but sparingly. Even on this occasion she manifested unmistakable, but decidedly mild evidence of an erotic excitement, not sufficient however to cause any interference with the operation, which was completed, and attended with a most happy result. The case which I have just narrated aroused several interesting and pregnant thoughts with regard to the danger which may possibly arise from the administration of this agent.

1. The danger of forming the cocaine habit.
2. The danger arising from the uncertain action of this drug. Cocaine, like chloral, at times, acts out of all proportion to the amount used.
3. As cocaine is comparatively a new drug there exists the danger of causing new, unexpected and unpleasant symptoms.

The first two of my observations are so well recognized that it is hardly necessary to give them more than a passing notice. All who have used cocaine to any extent can recall cases in which they regret having used the agent, and have also demonstrated that small doses have produced toxic symptoms out of all proportion to the amount of drug administered. We certainly should be more cautious in administering the agent, and always impress upon patients the danger attending its too frequent use. One-half grain usually produces its full physiological action; one grain may be considered a maximum dose. There exists a strong tendency among most men after they have used a certain agent for a long time without producing any serious or unusual effect to become careless and reckless in its application. The above fact remains true whether we know little or much about its physiological action and toxicology. I had until last summer, although thoroughly conversant with the then knowledge of the drug, doubted very much some of the asserted facts in connection with its toxicology simply because I had used the drug freely and frequently without any unpleasant effects. My first alarming case occurred in a female member of my own family, who was remarkably susceptible to the action of the drug.

The case we have just narrated presents to us

another interesting phase in the physiological action of the drug, *i. e.*, the excitation of the sexual desires. I am not a pioneer in this field of investigation, as equally interesting cases have been reported by Sandré, of Vienna, Cunningham, of England, and others. While both of the above-mentioned investigators called attention to these interesting symptoms, they did not take into consideration the possible medico-legal aspect. By medico-legal aspect I mean the possible danger that might result to a physician's reputation in case of the excitation of erotic symptoms in a female patient should they be alone. The question now arises as to the danger being a probable one. Is the danger as great as in its congener ether? Is there any danger of this character in the use of ether?

The last question I shall answer first. Ether, as we all know, in certain rare cases produces erotic symptoms of a most decided character, and many cases are recorded where there are evidences of the occurrence of complete venereal orgasm. Du Bois states that a woman under his observation requested, while being etherized, an attendant to kiss her, and after returning to consciousness stated that she had dreamt of having cohabited with her husband. I refer to the celebrated case of *Com. vs. Beach*<sup>1</sup> to illustrate the danger to reputation and liberty that has been caused by the occurrence of this symptom in the patient. This danger is so well recognized in the use of ether that no one would think of administering this anæsthetic to a female patient without the presence of witnesses.

Is the danger from this aspect as great as in the use of ether? We would at once answer this question in the negative. There exists a vast difference in the action of the two agents. In the one consciousness is destroyed, while in the other it is retained. The erotic symptoms produced in etherization occur during the stage of excitement, before there is a complete loss of consciousness, but there is a sufficient obtunding of the sensibilities as to cause the patient not to connect the relationship between cause and effect. In the eroticism produced by cocaine the patient is conscious—conscious of her surroundings and all that is occurring, although she may not be able to repress the feeling arising within her. In one case, supposing no attendant present, the patient remembers the dream, the sensations, and has no means of convincing herself that the physician has not taken advantage of her unconscious condition. In the other the patient, while experiencing the same sensations, is positively aware that nothing of that character occurred.

Is the danger a probable one? If all women were honest and non-hysterical we would certainly answer this question in the negative, but

as such is not the case it is a danger to be thought of, though of an minimal nature. It is only necessary to suppose the occurrence of such symptoms in a hysterical woman, who, on her return home becomes mentally unstrung—remembering only her sensations—it would be almost impossible to convince her that liberties had not been taken; or the occurrence of the same symptoms in a designing woman, there is danger enough.

DR. J. FORD THOMPSON thought he had been very fortunate, as he had been giving cocaine to men, women and children since its introduction and had never seen any such result as that reported by Dr. Richardson. He used it almost every day on different parts of the anatomy, but had not seen such an effect. He would be more careful in future, especially when administering it to females. He had, however, seen unpleasant effects in other ways. He thought a 10 per cent. solution was too strong for hypodermatic use; 4 per cent. is better, and 2 per cent. hypodermically will generally suffice. He thought that it might be used more frequently in the extraction of teeth. The reason for its failure in dentistry, he thought, was because the gum around the tooth to be extracted is generally painted instead of injecting the solution into the gum.

He had frequently seen irritation and inflammation produced about the incisions in operations. The worst effect he had ever seen was in a case of circumcision, in which he injected into the prepuce a few minims of a 4 per cent. solution of the muriate of cocaine. The man fainted and vomited. After the operation he went home, and when Dr. T. saw him the following morning there was an extensive inflammation about the penis and scrotum, which he thought was erysipelas. On the third day there was gangrene on the under side of the penis and scrotum. It was worse than any case of phlegmonous erysipelas he had seen, and in spite of the extensive sloughing it got well without contraction. It might be claimed that this case was due to septic instruments, but as he always attends to the cleansing of his instruments he was sure that they were aseptic. At that time he was accustomed to carry a solution of cocaine in little vials, which he now thought had undergone decomposition. Since then he had carried the tablets of cocaine and a vial of distilled water, and mixes the solution at the time of operation—and never uses what is left. He also takes the precaution of heating the needles of his syringe to a white heat before using them. He might be accused of being too careful, but since he has adopted this method he had not had an accident: there had been no failure to produce immediate effect; there had been no inflammation; and union of the wound had not been interfered with.

DR. BERMANN was accustomed to use cocaine

<sup>1</sup> Med. Jurisprudence and Toxicology, Reese, p. 559

every day and was glad to hear the report of Dr. R.'s case, as he had never seen any such excitement produced by the drug. This case might be classed with those idiosyncrasies in which the patient is particularly susceptible to the action of the drug. We see such unusual toxic effects from atropin and other drugs. The near approach of the menses may have had some effect in this case. He thought a 10 per cent. solution was too strong for hypodermic use in such a case. If it had been applied locally it would have answered the purpose. He had used a 20 per cent. solution in post-nasal surfaces without bad effects. He obtained good effects from a 5 per cent. solution if he waited a little while, or it might be necessary to repeat it. One lady to whom he had applied a 5 per cent. solution on cotton complained of nausea. A man objected to its use because it made him feel unpleasant a whole day, but experienced no erotic excitement. The gangrene in Dr. Thompson's case may not have been caused by germs, but by the contraction of the blood-vessels, which always follows the use of cocaine. He had had no experience with the hypodermic use of the drug, as he had always obtained the desired effect from its local application. He had painted the mucous membrane of the nasopharynx with a 5 per cent. solution and anesthetized the part.

DR. MURRAY was glad to hear Dr. Richardson's paper. It suggested the possibility of overdosing with cocaine, a possibility forcibly emphasized by the literature of the subject. Within a little more than two years after the introduction of cocaine as an anæsthetic Dr. Mattison, of Brooklyn, had collected and published the records of six fatal cases, and ninety in which poisoning to a greater or less extent had occurred. Cocaine seemed to be elective in its action, influencing different centers in individual cases. Dr. Schadle, of St. Paul, Minn., has reported two cases in which the sexual organs were affected; in one the patient's powers were stimulated and in the other impotence was induced. Mr. Mayo Robinson, of England, reports a case in which aphasia, lasting four hours, followed the application of cocaine for the removal of nasal polypus. The fatal case reported by Dr. Simms, of Philadelphia, showed the respiratory center to be most affected. He *thought cocaine dangerous* and agreed with Dr. Thompson that strong solutions should be avoided. He used cocaine as little as possible, had substituted electricity, using constant current, in cases in which he desired to relieve obstruction due to engorgement of the erectile tissue of turbinated bodies. It acted as quickly and nearly as efficiently as cocaine, and was valuable in such cases for its tonic action. Cocaine frequently applied he believed harmful to mucous membrane.

DR. THOMPSON would call attention to the use

of cocaine in tracheotomy. He had used it for this operation in two adults during the past two weeks. He introduced the solution hypodermatically along the line of the incision and there was no pain during the entire operation. This use will be still more important in children. During anæsthesia from ether and chloroform there is spasm of the glottis and the surgeon is compelled to hurry with the operation; but with the use of cocaine he can take his time. In neither of the two cases referred to was there hæmorrhage. Painting with cocaine is of little use in surgery. He had tried it in dilating the female urethra, but there was intense suffering. It may obtund the sensibility in mucous membranes but it is not always satisfactory in this use.

DR. RICHARDSON, in closing, said he did not consider 10 minims of a 10 per cent. solution too large a dose when we take into consideration that we were dealing with a patient in a normal condition. He had frequently operated upon the septum and always failed to produce complete anæsthesia by local application of the drug. He doubted the possibility of a 4, or even a 10 per cent. solution causing sufficient lowering of sensibility of this part to render operations painless; at least, such had not been his experience. It was only last Monday that he operated upon a young man of considerable courage, for a deflected septum. In order to render the operation painless he first painted the septum with a 5 per cent. solution of cocaine, and after a few moments tested it with a probe and found the mucous membrane quite sensitive. At the request of the patient, in whom he had used a 10 per cent. solution twice before, without unpleasant effect, he resorted to a solution of similar strength. Within a minute after painting the septum he noticed his patient become markedly pale, his hands were cold, pulse weak and rapid, and he complained of sickness and faintness—in other words, toxic effects. The patient was quickly restored. Even after the production of toxic symptoms the operation was excessively painful. This case also demonstrates the uncertainty of the action of the agent. We all know that the naso-pharynx is not as sensitive as other portions of the upper air-passages. Twice during the past month he had removed adenoid growths from this region—an operation occupying nearly half an hour—without the use of an anæsthetic. One of these was a boy of 15, the other a young lady of 22 years. Both suffered some pain, but, nevertheless, were capable of jesting during the operations.

DR. I. BERMAN read a paper on

#### THE POSSIBILITY OF LATENT SYPHILIS CAUSING INFECTION.

About sixteen months ago Mr. N. N. brought his wife to me for treatment for some throat trou-

ble, which had been existing for some time. One look at the lady's throat was sufficient to show me quite extensive ravages of syphilis. I at once took her husband into an adjoining room and put the question to him whether there was any possibility of her having been infected by him. This was denied. Under the circumstances, remembering that tuberculous lesions of these parts, in rare cases, can resemble very much those of her's, asked him whether any member of her family had died of consumption. This was confirmed by him very decidedly, so that I resolved, no special hurry being necessary, to leave the diagnosis for the present in suspense, until I had made a thorough examination of her chest and examined the sputum for bacilli. I gave her a disinfecting spray for the throat and nose, touched the ulcerations with lapis in substance, and waited for the developments which the microscope would afford us. Next day the sputum was brought, examined, and found to be free from bacilli. When they came again, which was after about three days, I took the gentleman aside and told him I had no doubt the disease was syphilis, and must be treated at once as such. He begged me to do exactly what I thought was proper, and I prescribed a 33 per cent. solution of iod. potass., of which 25 drops were to be taken three times a day, between meals, besides advising that the disinfecting spray should be continued and that she should come to see me every other day. I will here describe the nature of her lesions. Both tonsils were covered with ulcerations, another was on the pharyngeal wall, the arcus palatæ uvula was on the left partly destroyed, which the husband ascribed to the use of nitric acid, with which he had tried to cauterize it before coming to me. Rhinoscopic inspection showed extensive ulcerations in the post-nasal cavity, and the laryngoscope revealed a tumefaction over the right erythremoid cartilage, somewhat resembling a syphilacci. I found it necessary, in view of these lesions, to make a thorough general examination, which, however, furnished only negative results. There is no need of going into further details of the case, as I do not think that you will doubt the existence of syphilis. How the infection took place was a very interesting point to me, and I inquired of the husband, whom I had asked to call and see me alone, whether he had any lesion of doubtful character on his person. I was not satisfied with a negative answer, and asked permission to examine him. This was granted, and a thorough examination revealed nothing but a few infiltrated glands in the groin. The lady improved so rapidly that after a fortnight, apart from the destroyed portion of the soft palate, there could not be found a trace of anything resembling syphilitic lesions, and to this day, sixteen months since I first saw her, she has been not only absolutely free from all symptoms of

syphilis, but her general health has improved to such an extent that I failed to recognize her when I saw her a few months ago on the street, she having grown quite stout.

Some months after the lady had been discharged by me, at least for the present, as cured, her husband came to consult me in regard to his health. He complained about some symptoms of catarrh, but especially about a feeling of lassitude and general debility, which seemed to make all work, both physical and mental, a great effort to him. He imagined also that he had some kidney trouble. I told him that his case interested me very much, but that before I could do anything for him he would have to answer me some questions. These questions I put and his answers are contained in the following history: Is 45 years old; father died when 70 years of age of morbus Addisoni. Mother living, nearly 80 years old. No brothers or sisters. About 18 years ago he was treated for syphilis—according to his description an Hunterian chancre, sine exanthemata—with biniodide of mercury, for some time. The chancre disappeared very quickly and no sequelæ, that he is aware of, followed. I will here state that after I had told him my views of the case he was perfectly willing to give me all information in his power, and was very candid in his answers. He was married in the summer of 1872, believing himself perfectly well and being assured to that effect by his physician. There are no children to the marriage, and only one miscarriage occurred after two months. None later, and his wife did not complain of sore throat until eight years afterwards. At no time had he any sore throat or ulcerations in his mouth or throat, nor anywhere else, as a repeated thorough inspection demonstrated also to me. At least I could not find any cicatrices which are so characteristic of syphilitic lesions. Of course my diagnosis in his case was latent syphilis, and as he was very much run down I put him for the beginning on syr. ferri iod., 10 gtt., three times daily. Under this medication he improved rapidly, gaining 20 pounds in about six weeks, and said he felt much better than he had for years. Of course I informed him that his case would require prolonged supervision and treatment, and last fall I submitted him to mercurial treatment with hypodermics of bichloride, as he was complaining of dolores ostocopi, followed afterward by kal. iod. for six weeks. He has been getting on very well under this treatment, but has had now and then infiltration of submaxillary lymphatic glands, also of the præauricular glands. Repeated inspection of larynx and pharynx at that time gave always negative results, and the infiltration of the glands disappeared very soon under application of tinc. iod. and kal. iod. given internally. He feels perfectly well and strong now, and makes the impression of being in perfect health. Whether

he will remain so is a question that only time can answer, and I am still keeping him under supervision.

The natural conclusions which this case seems to allow us to form as decidedly as can be done under the circumstances, seems to me, that an infection of syphilis can take place through an individual afflicted with latent syphilis, probably through seminal fluid or other secretions.

THE PRESIDENT: Did she cohabit with any other than her husband?

DR. BERMANN could not answer this question definitely. The only interesting point in the paper is whether a woman could be infected by her husband eight years after marriage and eleven years after he had been treated for the primary lesion of syphilis, without any manifestations of syphilis during this period?

DR. THOMPSON thought that if the woman caught the disease from her husband it must have been when she became pregnant. The semen is not directly contagious; the child gets it from the semen and the woman from the fetus. The physiological fluid itself is not infectious.

DR. SMITH: Will a hypodermatic injection of the seminal fluid of a man suffering from syphilis produce the disease in an uninfected individual?

DR. THOMPSON thought not, but had never seen it tried. He did not think that the syphilitic bacillus was in either at this late date. He would also question the benefit of mercury at this time of the disease. If it were syphilis it was the tertiary form. Neumann divides his cases into three classes: in one he does not give any mercury; in the second he gives mild doses; and in the third he gives heroic doses. In the tertiary form of the disease hypodermatic injections of mercury would not be of much benefit. The children of parents with tertiary syphilis are not syphilitic, but have scrofula or struma. He did not believe in the presence of syphilitic bacilli in the tertiary form of the disease. There is no virus in the suppurative and later stages, and the fluids of the body are not inoculable.

DR. BUSEY: According to Dr. Bermann's statement the man has had syphilis for eleven years; three years after the primary chancre he had married, his wife became pregnant and aborted at the second month on account of syphilitic infection, and eight years afterwards syphilis became manifest. Is it possible for a man to have latent syphilis for eleven years before the development of secondary or tertiary manifestations? and a woman to become infected by her fetus and not exhibit symptoms of the disease for eight years? From the history he would suppose that the woman contracted syphilis long after that miscarriage.

DR. BERMANN: The man had been treated for syphilis two years before his marriage; his wife miscarried at the second month of her married

life; and eight years after she had syphilitic lesions of the soft palate. She did not contract the disease from anybody else; then the latent symptoms in the man produced the secondary symptoms in the wife.

DR. BUSEY: There were two remarkable coincidences which he was not quite willing to accept. It would seem that the only way for the woman to have become infected was through the pregnancy, and if that was so there would have been earlier manifestations of syphilis. He thought she contracted the disease subsequently. He doubted the duration of latent infection. He did not believe either the history of the man or of the woman. It must be demonstrated that a man could have a Hunterian chancre and then infect his wife eleven years after, before he could accept it.

DR. BERMANN: If the woman had had syphilis during this term of years more of the soft palate would have been destroyed. He was confident that she contracted it just before seeking his advice. Here we have a syphilitic husband constantly cohabiting with his wife, then why could not the latent disease take on fresh action and thereby cause infection in the wife?

(To be concluded.)

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*Dr. Janeway on the Diagnosis and Treatment of Basedow's Disease—Dr. J. Lewis Smith on Idiopathic Contractions, or Tetany in Infancy and early Childhood.*

The last meeting of the New York County Medical Association for the present season was an unusually attractive one; valuable papers by Professors E. G. Janeway and J. Lewis Smith constituting the main features of scientific interest. Dr. Janeway's was on "The Diagnosis and Treatment of Basedow's Disease," and in it he said his object was not to include the whole range of this affection, but rather to present some points derived from his personal observations in a considerable number of cases which might be of practical service. When well developed and presenting all the marked features characteristic of it, exophthalmic goitre could be at once recognized by any tyro; but the case was very different in the incipency of the disease, or when some of the characteristics were obscure. Thus, at the beginning the general state of the patient's health was not infrequently more apt to strike the physician than the distinctive features of Basedow's disease, and sometimes perhaps lead him to give a wrong name to the malady.

Of the three terms most commonly used to conceal the absence of definite knowledge regarding the disease present in more or less obscure cases: neurasthenia, malaria and lithæmia, the two former are occasionally applied to this disease. As regards the neurasthenia, the presence of nervous debility gave some ground for its use, while in other cases the patient not only grew weaker, but had a sense of heat, or even elevation of temperature; thus making the diagnosis of malaria plausible. The adoption of either of these terms, however, was of bad import for the patient; for the treatment appropriate to these conditions would not be successful in Basedow's disease. Dr. Janeway said he had known even a supposition of phthisis to exist, on account of the emaciation, loss of strength, and sense of warmth present, sometimes in connection with a cough due to an intercurrent cold or to congestion dependent upon enfeeblement of the heart. In such cases the goitre present might press on the larynx and trachea, causing congestion of these parts; while the enlarged heart was liable to cause some congestion of the lungs, and of itself produce some dulness. Moreover, from these causes a modification of the respiration occurred, and patients with advanced Basedow's disease had been thought to die of pulmonary tuberculosis when none was found at the post-mortem examination.

Each of the three factors of the disease, exophthalmus, goitre and palpitation, he went on to say, may be used as a designation of a disease, without having regard to the nature of the process. It is not uncommon for the exophthalmus to be overlooked by the patient and his friends, owing to its gradual supervention. Graefe's diagnostic rule, that the upper lid does not follow the eyeball, as in the normal state, in looking downwards, is not a certain criterion, for we may not find it in all cases where slight exophthalmus exists. Moreover, he had seen it present in one eye, and absent in the other. An experienced physician can often detect the exophthalmus where its presence has been hitherto unsuspected; and an excellent test is to ask old acquaintances who have not seen the patient for some time their conclusion in the matter. It is to be remembered, of course, however, that every case of exophthalmus is not dependent upon Basedow's disease.

The enlargement of the thyroid gland may deceive by its presence or mislead by its apparent absence. In the milder cases the slight growth or vascular engorgement of the thyroid (the patient in the meanwhile having grown thinner), may keep the neck of only normal fulness. Attention, however, to the condition of the circulation in the neck will serve to prevent misconception. Even when the thyroid is but little enlarged, the peculiar vascular turgescence, arterial thrill, and arterial and venous murmurs can be made out. When the thyroid is enlarged the thrill is

particularly noticeable in the superior thyroid arteries; while when this is not the case, he has felt it rather in the carotids themselves. Basedow's disease has sometimes been mistaken for aneurism, on account of the enlargement, thrill and accompanying murmur; and this is particularly apt to be the case when the enlargement is predominantly on one side. An occasional case will present the difficulty of deciding whether the disease present is an illustration of parenchymatous goitre accompanied by palpitation or is really Basedow's disease.

The condition of the heart, Dr. Janeway said, may be misleading in several ways:

*First.* Basedow's disease may complicate organic heart disease of præexistent date.

*Second.* At times it becomes difficult to determine whether a murmur of mitral insufficiency is due to an old lesion or is dependent upon muscular incompetence or relative insufficiency of the mitral valve. He has known hearts considerably enlarged as far as the left ventricle was concerned, and having well marked systolic murmurs audible posteriorly, yield under treatment to such a degree that the murmur disappeared and the heart returned to a nearly normal size. This constitutes one of the greatest liabilities in the way of diagnostic error in cases possessed of moderate goitre and exophthalmus, as the tendency is to consider the case one of incurable cardiac disease. In certain cases, to which he thinks sufficient attention has not been paid, the patient will suddenly fall or have his legs give way under him; but almost immediately will be able to resume the standing position or walk. The question of cerebral or spinal disease may be raised in connection with these; but the rapidity of the occurrence and of its disappearance disprove such a supposition. The cases in which he has met with it have been weakened by diarrhoea or vomiting, or as a result of the malnutrition accompanying the disease, and, under excitement or physical exertion, have had an extremely rapid heart action.

*Third.* As previously mentioned, the congestion of the lungs from the weakened heart may raise the question of phthisis.

*Fourth.* Cases are met with of palpitation without exophthalmus or goitre, but having, as far as the heart and the general condition are concerned, phenomena identical with those occurring in exophthalmic goitre. Such cases he has been accustomed to consider as allied to Basedow's disease.

As to the condition of the heart in this disease, his experience is that cases occur without any very marked enlargement, while others are met with in which, with an antecedent history of freedom from cardiac disease, hypertrophy with dilatation is produced by the Basedow's disease. Irritable vomiting is at times a distressing accompaniment of the disease, and may cause death

The treatment, Dr. Janeway said, must have relation to the condition of the circulation, to the accompanying anæmia, and to any coexisting irregularity in the functions of the body, especially menstrual disorder. It must not be forgotten, however, that menstrual irregularity may be a result as well as a cause of the trouble. One of the most prominent features in the treatment consists in finding an agent which will quiet the rapidity of the heart's action, and his experience had led him to give up the use of digitalis for this purpose. Formerly he employed tincture of aconite to a considerable extent, and he has seen good results from it in cases where, but for the name of the disease, he would not have ventured to use it. As a rule, the best results have been from the continued use of small doses.

Of late, however, he has employed the tincture of strophanthus in doses of 5 minims three times a day, gradually increased if necessary. Of eight cases in which it was used, three have been lost sight of, while in two a cure has occurred; the only other remedy employed being iron. In one other, complicated with mitral insufficiency and considerable dilated hypertrophy of the left ventricle, there has been a cessation of the palpitation and a considerable improvement in the heart's condition. In the seventh case recovery occurred, but galvanism was also used. The eighth patient had such irritable vomiting that it was impossible to give the remedy, or even to administer much food, by the mouth, and she succumbed to the exhaustion of the disease and vomiting in a neighboring city, after she had passed from his immediate observation. On the whole, the results from strophanthus have been such as to convince him of its real utility in this disease. He has found it to succeed sometimes in cases where digitalis had failed, and he prefers it to aconite as less dangerous, particularly in cases where the heart is somewhat enfeebled. He tried spartein in two cases, but in neither of them did it prove of much service.

It is worthy of note that electricity, which has been highly lauded by some authorities, in this disease, has been of little value in his hands; and the same result was given by Dr. Alfred L. Carroll and others in the discussion of the paper. It was formerly Dr. Janeway's custom in all cases to advise galvanism, in conjunction with iron and some cardiac remedy; but he stated that he has not had a single case of cure where galvanism alone was used. The recent good results obtained by him from strophanthus and iron seem to render it probable that the benefit formerly noted when galvanism was resorted to was in reality due to the remedies used in conjunction with it. Personally, he has not used atropia, though he has seen cases in which it has been used, but without favorable result.

Rest, both physical and mental, is a necessary

adjuvant in the treatment, as well as the avoidance of worry and emotional excitement. He thought it reasonable to suppose that the condition of the circulation in this disease tends to produce the restlessness, often associated with insomnia, met with in some cases; and in a certain proportion of these it will yield to the ordinary treatment of the disease. Sometimes additional remedies are required, and in one case he has used sulfonal with good results. Formerly choice had to be made of the bromides, morphia (or, preferably, codeia), and chloral, or the use of the bath or wet pack. Iron is not invariably necessary, but is usually indicated by the coexisting anæmia. Attention should be paid to the condition of the nutrition, as evidenced by the appetite and general feeling and by the weight of the body; and whenever this is at fault appropriate measures adopted for its improvement. In conclusion he said that confidence on the part of the physician that he can produce an amelioration in his condition is of decided benefit to the patient. Moreover, it has seemed to him that hospital and dispensary patients are less amenable to treatment than those in the better walks of life; for where fright or worry is a prominent factor in the production of the disease, as is often the case, it certainly does not add to the efficiency of the treatment to have the patient surrounded by the sick and dying.

An interesting discussion of the paper was participated in by Drs. Carroll, Hepburn, MacGregor, Oberndorfer and J. Lewis Smith, and by the President, Dr. C. S. Wood; and in closing it Dr. Janeway said that certain points had been brought up by some of the speakers which he had not touched upon in the paper. Thus, he had not referred to the pathology, for the reason that this was so extremely obscure. In some of the cases in which autopsies were made the cervical sympathetic had been found entirely normal, and this would certainly disprove the hypothesis that the lesion of Basedow's disease is located in this portion of the nervous system. More recent investigations would seem to show that the trouble originated, either directly or indirectly, in the medulla oblongata. As to the starting-point of the disease from a clinical point of view, it would not do to always attribute this to such a cause as fright or emotional excitement. In one of the cases mentioned in the paper, where the patient was a lawyer of distinction, there was no fright, no special anxiety, and no mental strain from overwork. In this instance a complete recovery followed the use of strophanthus and iron. It was a well established fact, however, that a good many of the cases do originate from fright, worry or emotional excitement; and hence the disease was more common in women than in men, though he had met with a considerable number of cases in males.

He thought it advisable to avoid, if possible, the use of such agents as opium, as sooner or later the nutrition would become affected by the drug; and it was of the highest importance that the nutrition should be maintained as perfectly as possible. He had met with cases in which straphanthus and other appropriate remedies produced no effect as long as the nutrition was impaired; but when this had become improved the distinctive features of the disease began to subside under their use. In neuralgias also, and all chronic nervous diseases, he disliked to use opium for the same reason. There were, however, certain cases of Basedow's disease attended with rapidity of the heart's action in which nothing acted so efficiently in controlling this symptom as opium; and the same was true in some cases of aneurism in the region of the neck.

Dr. J. Lewis Smith's paper was devoted to the subject of "Idiopathic Contractions, or Tetany, in Infancy and Early Childhood." Having given a *résumé* of the literature of the disease from the time it was first taken up by the French writers in 1831, he stated that the term tetany is applied to an affection which is characterized by tonic contraction of muscles, commonly those of the extremities, but sometimes also those of the face or trunk, produced by causes external to the nervous system, and usually of temporary duration. In tonic muscular contractions arising from disease of the brain, spinal cord, or their meninges, or of the nerves supplying the affected members, the contractions are not the malady itself, as in the case of tetany, but are merely symptoms of a disease located elsewhere.

Tetany may occur at any age, but is most frequent in infancy, in early childhood, and in early adult life. As a rule, there appears to be no hereditary predisposition to the disease, but the occasional occurrence of multiple cases of the disease in families would seem to show that there may perhaps sometimes be an inherited neuropathic tendency. Nearly all writers assign the most important place in the causation to diseases of the digestive apparatus. Thus, Trousseau states that in the cases coming under his observation diarrhœa was commonly present (many cases met with in 1854 following cholera); but in one instance the cause seemed to be obstinate constipation. Dr. Smith then related in detail a case of his own, occurring in an infant, in which constipation was the only assignable cause; after which he went on to say that Erb states that all forms of intestinal disease may cause tetany, but that it especially occurs after protracted and exhausting diarrhœa. Gowers also regards diarrhœa as the chief cause. There is no recorded instance in which lumbrici or ascarides caused the contractions; but Gowers alludes to three cases caused by tapeworms. Remarkable as it may seem, dentition *per se* is but seldom a cause of tetany; but in

a case which Dr. Smith related, which he saw in consultation with Dr. Janeway, teething was regarded, after repeated and thorough examinations, as the chief cause of the trouble. The child was 20 months old, and the gums were found swollen and congested over the crowns of five advancing teeth, which appeared to be in nearly the same stage of development, and were evidently soon to protrude. The contractions continued for three weeks, by which time all, or nearly all, the imprisoned teeth had escaped; and after this there was never any return of the tetany. Speaking further of the etiology, he said that tetany is more liable to occur in those whose systems are enervated by preëxisting disease than in those who are robust. Billroth and Barthez, Erb, Gowers and others mention a number of febrile affections as a sequel of which it is liable to occur, and Gowers also states that in young children attacked by it indications of rachitis are rarely absent. Another recognized cause of tetany is exposure to cold, and hence it has been regarded by some as in reality a rheumatic affection. In infancy and early childhood, however, other causes are apparently much more common than taking cold.

Dr. Smith then gave the following clinical picture of the disease: Ordinarily tetany occurs without any marked premonitory symptoms, but in some instances it is preceded by pain in the head or spine, vomiting without any previous indigestion or gastric disturbance, and a general feeling of indisposition. Usually, in those old enough to express their sensations, it begins with tingling, burning, or other unusual sensory manifestations. The tonic contractions occur suddenly, and sometimes simultaneously in the upper and lower extremities. Rarely the contractions occur in the muscles of the upper extremities alone, or in the muscles of the trunk. At first a feeling of stiffness is experienced, and this is followed by the tonic contraction, with the fixation of the affected part in a state of persistent flexure or extension. As regards the upper extremities, the contraction of the thenar and hypothenar muscles usually causes hollowness of the palms of the hands; the first phalanges of the fingers are flexed, the second and third phalanges extended, and the thumb adducted and flexed. Usually the hand is slightly flexed, as is also the forearm. The muscles which move the arm commonly escape, but exceptionally there is adduction of the arm on the shoulder. The hand may be extended, instead of flexed, and all the points of the fingers extended; or they may all be flexed, and the first closed.

The thighs may be adducted or flexed, the foot extended, forming a talipes equinus, and the toes flexed. In cases of ordinary severity the contractions are limited to the muscles of the extremities, and are more marked and persistent in those which move the hands, feet, fingers and

toes than in other muscles; but in the severer cases the muscles of the trunk and head participate. Contraction of the abdominal muscles produces rigidity of the abdominal walls. Spasm of certain of the thoracic muscles occasionally occurs, causing dyspnoea, and even lividity; and in some of these cases of embarrassed respiration the diaphragm is probably involved. Opisthotonos, retention of urine, antelexion of the neck from contraction of the sterno-mastoids, fixation of the jaws from spasm of the masseter, retraction of the angles of the mouth, stiffness of the tongue, and indistinct articulation, are occasional symptoms in severe cases.

The contractions render the affected muscles hard and unyielding, and the child cries from pain when attempts are made to straighten the limb. If the spasm be slight, some voluntary movement of the affected muscles is possible, though it is restrained and difficult; but in severe cases voluntary motion is impossible. Unless the attack is very mild, pain in the contracted muscles such as everyone experiences when a spasm occurs in the calf of the leg. It may occur in paroxysms, with distinct intermissions, or without interruption; and it may vary at different times, probably from some variation in the degree of spasm. Certain subjective symptoms, such as numbness and tingling, which sometimes occur in tetany, may continue during the intermissions. After some hours or days the rigidly contracted muscles relax and the disease disappears, except, perhaps, that a degree of stiffness remains. But the respite is usually of short duration. The spasms recur, and several successive recurrences and intermissions take place, running over weeks and months, before the disease is permanently cured. During the intervals in the contractions the affected nerves and muscles are in ordinary cases unduly excitable; so that sudden pressure or percussion causes some contraction. It was Trousseau who first noted that, as a rule, compression of the artery and nerve supplying the contracted muscles causes or increases the contraction. Dr. Smith said it was an interesting fact that in cases which he has observed the spasms did not cease in sleep, though perhaps the contraction of the muscles was not as great as when the patient was awake.

Gowers, Erb and others have noticed that the electrical excitability of the nerve which supplies the contracted muscles is increased; but occasionally in long-continued cases the muscles undergo a certain amount of atrophy, which is attended by diminished electrical irritability. When the contractions are strong oedema sometimes occurs, especially upon the dorsal surfaces of the hands, and Henoch attributes this to compression and consequent passive congestion of the veins. In some cases perspiration is sometimes noted, and an erythematous redness may appear over the affected muscles. Occasionally in acute attacks

the temperature is moderately increased, but ordinarily it is normal.

The pathology of tetany, Dr. Smith said, was still involved in great obscurity, though it was supposed that the motor cells of the spinal cord and the axis cylinders are in some way affected. As to its diagnosis, the bilateral and symmetrical nature of the affection was a point of great importance, and the fact that certain groups of muscles on the two sides were affected enabled us to distinguish it from the muscular contractions due to central lesions of the nervous system. Moreover, the spasms in tetany, as had been seen, were as a rule attended with intermissions, and the nerves over the affected area were increased in sensitiveness, while spasms could be produced by compressing the latter; thus forming a further contrast to the symptoms present in muscular contractions produced by disease located in the nervous centers or in the nerve supplying the affected muscles. With regard to prognosis, he said that tetany, whether intermittent, remittent, or occurring with little daily variation, sometimes soon ceases, and does not return; while in other instances it does not cease altogether for months, although varying in severity at different times.

In speaking of the treatment Dr. Smith said that the cause or causes of the attack, so far as ascertained, should obviously receive prompt attention. The bromide of potassium is a most useful remedy, and it should be given in decided doses; 4 grs. every three hours being required for a child of from 18 months to 2 years of age. Chloral, Indian hemp, and chloroform by inhalation, are also of service in allaying the spasms. Chloroform is said at first to increase the spasms, but they cease when the patient is fully under its influence; though liable to return when the inhalation is discontinued. Hauber states that two cases which were not relieved by other treatment were soon cured by active massage practiced when the patients were under chloroform narcosis. Stimulating liniments containing chloroform, applied over the affected muscles, have also been found of benefit in some instances. In his remarks on the electrical treatment of tetany Gowers states that faradism is contraindicated, but that good results have sometimes been obtained from the voltaic current. When rachitis is present, cod-liver oil, lime, and syrup of the iodide of iron are rationally indicated; and since so many cases originate from gastro-intestinal disorders, it is important that the diet should always be bland, easily digested and nutritious.

P. B. P.

ENGLISH authorities have concluded that dynamic cooling, if not the sole cause of rain, is at all events, the only cause of any importance, all other causes being either inoperative or relatively insignificant.

## BOOK REVIEWS.

TRANSACTIONS OF THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION. Vol. I, Session of 1888. Caldwell Printing Co., Birmingham, Ala.

This is a well appearing volume containing some thirty papers. Asepsis in surgical procedures is emphasized by several essays, entitled, "Antiseptic Surgery in Country Practice," by J. M. Taylor, M.D.; "Practical Aseptic Surgery," by J. W. Long, M.D.; and "Aphorisms in Antiseptic Surgery and Gynecology," by F. T. Meriwether, M.D.

We notice that S. M. Hogan, M.D., in "Treatment of Strictures of the Urethra by Electrolysis," according to the method of Dr. Robert Newman, of New York, meets with gratifying success, further that J. D. S. Davis, M.D., has treated enlarged prostate by electrolysis, following also the teachings of Newman, whose electrode he uses. This is introduced, after first being lubricated with glycerine, never with oils, into the prostatic urethra. It is then made the cathode or negative pole for a current of from 5 to 10 milliamperes. This current may be continued from ten to fifteen minutes. The anode should be applied to the back or hips. It should be understood that while physically there may be no difference between a current of 55 milliamperes continued for five minutes and a current of 5 milliamperes for fifty-five minutes, there is in fact a great physiological and therapeutic difference. In the former a chemical galvano-cauterization would result, while in the latter a galvano-chemical absorption, which the author defines as a chemical decomposition, which borrows its immediate effects from the separated non-nitrogenous bodies, there generating warmth, relaxation, softening and absorption of tissue. This is the character of current to be used in enlarged prostate. The other electrolytic action, known as chemical galvano-cauterization arises from the decomposition of salts which set free acids at the positive and bases at the negative pole, and said acids or bases attacking the tissues in their vicinity, giving rise to a caustic action chemical in its nature. The author quotes Apostoli, who expresses it very clearly in the following words: "The effect of electrolysis is, therefore, entirely analytical, and prepares for the subsequent caustic action, which is rather synthetical."
